MENFORMON TABLETS

to reverse menopausal changes

Tablets of
1,000 I.U.
3,000 I.U.
10,000 I.U.
each.

"There are, of course, certain more severe sequelæ of the menopause, which demand much higher doses"

PROC. ROY. SOC. MED. July, 1936. p. 1094.

" As a guide to the adequacy of the dose it may be suggested that results are to be expected in terms of days rather than of weeks . . . The amount may as well be increased promptly to this point of complete restoration of comfort."

J. AMER. MED. ASSOC. Vol. 104. 625 (1935)

IODATOL

(Iodised Oil B.P.)

The value of iodised oil in bronchography is emphasised in a recent report (*Archives Med.-Chir. de l'App. Respiratoire*, 12; 345 (No. 5) 1938). Iodised oil was used with marked success and freedom from unpleasant sequelæ in the diagnosis of bronchial dilatation in various forms of pulmonary tuberculosis.

Reports similar to the foregoing of the value of iodised oil as a contrast medium in radiography continue to appear and its value, as suggested by inclusion in the Addendum to the British Pharmacopœia, is now firmly established. Iodised oil (B.P.) is available as Iodatol in bottles of 20 c.c. and 30 c.c.

2nd Edition. 4 Coloured Plates and
253 Text-figures. 18s.

"It is a first-class and lucid presentation of sane and sound gynaecological practice of to-day . . . will, doubtless, continue its wide appeal, and further editions are certain to be required."

—JOURNAL OF OBSTET. AND GYN.

**A SHORT TEXTBOOK
OF MIDWIFERY**

By G. F. GIBBERD, M.S.,
F.R.C.S., M.C.O.G.

Assistant Obstetric Surgeon,
Guy's Hospital.

187 Illustrations. 15s.

"The author and publishers deserve the greatest possible praise for this work, which is of a practical character, illustrated by excellent photomicrographs and line drawings . . . is undoubtedly one of the best books available on the subject of modern midwifery."

—THE PRACTITIONER.

MEDICINE**TAYLOR'S PRACTICE
OF MEDICINE**

15th Edition. Revised and Edited by
E. P. POULTON, D.M., F.R.C.P.

Physician to Guy's Hospital,
and Collaborators.

71 Plates (16 Coloured) and 104 Text-
figures. 28s.

" . . . is still the leading text-book in the English language."

—THE MEDICAL PRESS AND CIRCULAR.

**CHEMICAL METHODS
IN CLINICAL MEDICINE**

By G. A. HARRISON, M.D.,
B.Ch., M.R.C.S., L.R.C.P.

Reader and Lecturer on Chemical
Pathology, St. Bartholomew's
Medical College.

2nd Edition. 3 Coloured Plates and 86
Text-figures. 21s.

"Has undeniable claims to first place in any list of books on chemical pathology."—BRITISH MEDICAL JOURNAL.

**MEDICINE
ESSENTIALS FOR
PRACTITIONERS AND
STUDENTS**

By G. E. BEAUMONT, D.M.,
F.R.C.P., D.Ph.

Physician to The Middlesex Hospital.

3rd Edition. 74 Illustrations. 21s.

"We regard this publication as, for its size, the most valuable recent book-contribution to medicine."

—EDINBURGH MED. JNL.

**THE SCIENCE AND
PRACTICE OF SURGERY**

By W. H. C. ROMANIS, M.B.,
F.R.C.S., and

PHILIP H. MITCHNER,
C.B.E. M.S., F.R.C.S.

Surgeons, St. Thomas's Hospital.

6th Edition. 800 Illustrations.
2 Vols. 28s.

"This excellent text-book needs little recommendation. It has proved its worth, and has now held its place for many years as a guide to the student preparing both for qualifying and higher examinations."—THE LANCET.

**A SHORT TEXTBOOK
OF SURGERY**

By C. F. W. ILLINGWORTH,
M.D., F.R.C.S.(Ed.)

Lecturer in Clinical Surgery,
University of Edinburgh.

8 Plates and 179 Text-figures. 21s.

"It covers the whole field of surgery and should prove invaluable to the student as the important and common surgical conditions are dealt with 'in extenso' . . . will take its place as one of the really valuable books which students require."—THE MEDICAL PRESS.

**A TEXTBOOK OF
SURGICAL PATHOLOGY**

By C. F. W. ILLINGWORTH,
M.D., F.R.C.S.(Ed.), and

B. M. DICK, M.B., F.R.C.S.(Ed.)
Lecturers in Clinical Surgery,
University of Edinburgh.

New (3rd) Edition. 299 Illustrations. 36s.

"This is an excellent account of Pathology as the surgeon is expected to know it . . . well adapted to the needs of candidates for the higher surgical degrees . . . a useful work of reference for the practising surgeon."

—BRITISH MEDICAL JOURNAL.

IMPRESSIVE OPINIONS OF

HEILBRUNN'S

NEW

NEW

Outline of General Physiology

From the EDINBURGH MEDICAL JOURNAL

"It is hard to understand why a man should want to write a book," says Professor Heilbrunn in his preface. He goes on to say that he has been driven to write this one to meet the needs of his own students. The somewhat diffident and apologetic air with which he thus presents the fruits of an enforced labour is completely belied by the extraordinarily high standard he has achieved in what is a most excellent work. It is indeed hard to understand how a man could write such a book. In a clear concise style Professor Heilbrunn gives an outline of the whole field of contemporary general physiology, without allowing the limitations of space to lead him into dogmatism on the one hand or over-simplification on the other. The ground covered is enormous, the examples are well chosen and the illustrations uniformly good. But the chief value of the book lies, perhaps, not so much in the quality of the text, admirable though this is, as in the references to the original literature which accompany it. These are so profuse and so well chosen that the whole work forms not only a first-class text-book, but a most valuable source book for the various branches of the subject as well. Professor Heilbrunn is to be congratulated on a remarkably fine piece of work."

From PROTOPLASMA (Berlin)

"General physiology is 'a science in its own right.' There is probably no text-book which presents this comparatively young science in a better or more impressive form than this new work by Heilbrunn. It radiates enthusiasm and devotion to the cause of knowledge and research, and so cannot fail to inspire with like enthusiasm those for whom it was written and to whom it is dedicated, namely, 'my students.' And so outstanding is the excellence of this book that all who read it will at once become the author's 'students,' as well as those who hear him lecture. Heilbrunn, with his almost fanatical love of truth, does not seek to simplify, steady by smoothing over the difficulties and debatable points of his subject; he simplifies it by co-ordinating all that is of fundamental importance and presenting it as a unity in clear and pregnant terms. Such an achievement is possible only to one who has mastered completely his extremely diversified material. The bibliography of this book is immense, and it is not merely quoted but thoroughly digested and incorporated. In every case it is completely up-to-date, including even the year of publication. This applies not only to the chapters dealing with protoplasmic questions, the author's special subject in which he is completely at home, but also to those on questions more or less remote. The plan, the whole structure of this book, is as arresting in its logical development as are the separate parts."

From THE LANCET

"Prof. Heilbrunn's object here is to provide an account of contemporary general physiology, and to include such references to original literature as will enable the reader to follow into further detail the subjects with which it deals. The book arose out of the author's teaching experience and the needs of his own students, especially those who have carried out research with him; it represents a mine of valuable up-to-date information and must have cost a fabulous amount of hard references alone should prove very valuable. This is the kind of general physiology that would have delighted Claude Bernard or Sir William Bayliss, and in fact is a modern presentation of that aspect of the subject to which they, in their own times, contributed so much."

We congratulate the author on his splendid work, and would prophesy that his modest hope that 'the book may have sufficient appeal to warrant a second edition' will be realised."

ADVANCES IN DIAGNOSIS

Edited by

SIR HUMPHRY ROLLESTON, BT., G.C.V.O., K.C.B., M.D., F.R.C.P. and ALAN MONCRIEFF, M.D., F.R.C.P.

The autumn Special Number of *The Practitioner* has come to be regarded as the outstanding medical publication of the year. The advances in diagnosis and treatment of the past twelve months are reviewed by twenty experts who interpret the progress of medical science in terms of practical, everyday medicine. The use of the modern clinical preparations of the sulphanilamide type is described for many disorders, the exact position of vitamins in diet is defined, and the modern management of rheumatic disorders is set out in detail. The correct approach to a patient with anaemia, the use of potamine insulin, modern views on bronchiectasis, and the latest advances in endocrinology are some of the subjects discussed.

ADVANCES IN MEDICINE

A NEW SPENCER DEVELOPMENT FOR SUPPORT DURING PREGNANCY.

Individually Designed for Each Patient

Exceedingly light in weight, flexible at points where flexibility is desired (notably at upper abdomen), this new Spencer design provides adequate support for the abdomen by means of a separate CONCEALED inner abdominal section. (Adjustment of inner support is the only daily adjustment required.)

Restful back support, lessening of backache induced by pregnancy and *posture improvement* are ensured by the corset's broad back and its abdominal section. In many cases it will prevent nausea and vomiting if worn during early months of pregnancy. It guards against sacro-iliac strain and lifts some of the weight from the blood vessels in the groin and helps to relieve discomfort from pressure. The strain of increasing weight of the abdomen is placed on the pelvic girdle—not on the spine at or above the lumbar region.

Test its efficiency for yourself by prescribing it for a patient who requires support during pregnancy. For service at patient's home or your Surgery, look in the telephone book under Spencer Corsetière or write direct to us.

ABOVE: The New Spencer Maternity Support shown adjusted. Note its smooth exterior. Its inner supporting section is concealed and its laces are recessed so they cannot show through outer clothing. Gives best possible figure-lines, is easily laundered, comfortable, economical, and guaranteed NEVER to lose its shape.

AT RIGHT: Inner supporting section which is instantly adjustable at several different points by means of flat tapes and self-locking slides.

BEWARE OF SUBSTITUTION.—Spencer Corsets Ltd. regret the necessity of warning the medical profession that in several instances where doctors have specifically prescribed a Spencer Support, a corset of another make has been substituted, and, because its makers do not understand the Spencer principles of individual designing, has been unsatisfactory. Every genuine Spencer Support bears the SPENCER Label.

Spencer Supports and Corsets are never sold in shops.

May we send you this New Professional Booklet describing Spencer Supports and their Accepted Uses?

MARMITE

YEAST EXTRACT
for vitamin B complex
in POLYNEURITIS

The close connection between polyneuritis and vitamin B₁ deficiency is well known. Not only is the polyneuritis of beri-beri considered to be due to deficiency of this factor, but so also is the polyneuritis associated with gastro-intestinal lesions, pregnancy, alcoholism and other toxic conditions.

Clinical tests have proved beyond doubt that Marmite therapy is effective in these cases of polyneuritis of nutritional origin. In a recent paper on peripheral neuritis, associated with pyloric stenosis and deficiency of vitamin B₁, it is recorded that the patient

"was advised to take Marmite, 2 drachms daily . . . made a gradual improvement and returned to work . . . still takes Marmite. . ."
(Lancet, May 7th, 1938, p. 1045.)

ANAHÆMIN B.D.H.

In the treatment of pernicious anæmia

It has been demonstrated for more than 2½ years that Anahæmin B.D.H. is unique in its hæmatopoietic effect in pernicious anæmia.

In many cases an initial dose of 2 c.c. followed by 1 c.c. fortnightly constitutes effective treatment. In those instances, however, in which it is impracticable to make periodic blood examinations, it is important that the patient should receive adequate medication; this can always be ensured without risk of untoward effects either by increasing the dose of Anahæmin B.D.H. or by injecting it more frequently.

LACTOFLAVINE B.D.H.
 (VITAMIN B₂).

It is established that lactoflavine constitutes a prosthetic group of an enzyme system concerned with the oxidative processes of all cells.

Considerable diversity in the symptoms of deficiency are therefore to be expected; among the symptoms described are those so widely apart as neural degeneration and cataract. Further, it has been stated that lactoflavine increases visual acuity in diminished light. Lactoflavine, there-

fore, may prove to have uses in ophthalmology.

It is of interest, also, that hens' eggs deficient in lactoflavine fail to hatch; it is suggested, therefore, that this substance may prove of value in certain cases of sterility of obscure origin in humans.

Lactoflavine B.D.H. is issued in ampoules of sterile solution for intramuscular or subcutaneous injection.

"ALOCOL"

Colloidal Hydroxide of Aluminium

Improved Antacid Therapy

SODIUM BICARBONATE, bismuth salts and other time-honoured antacids having each proved to possess individual disadvantages, an agent such as "Alocol" which combines the best therapeutic features of these with intrinsic merits of its own, must be of interest to the physician.

"Alocol" is a powerful antacid agent which forms with the stomach contents a colloidal jelly with the power of adsorbing free hydrochloric acid, thus fixing it and eliminating it from the system. It has a remarkably soothing effect on the inflamed or irritated gastric mucosa and is, therefore, rapidly effective in relieving pain. Being non-absorbable "Alocol" is free from any risk of "alkalosis."

"Alocol" can be prescribed with confidence in all cases where alkaline therapy is indicated. Issued in tablet and powder form.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

ALASIL

Better Salicylate Therapy

WHATEVER be the season of the year, there is a wide sphere of utility for "Alasil," the improved form of salicylate medication.

"Alasil" is a very definite advance on ordinary compounds of salicylic or acetyl-salicylic acid both in therapeutic efficiency and in freedom from the risk of unpleasant gastro-intestinal sequelae. This high tolerability is due to the fact that "Alasil" is composed of calcium acetyl-salicylate—the least irritating of the salicylate compounds—and "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid.

A careful series of experimental tests has shown that "Alasil" is more completely absorbed than ordinary salicylate compounds and that it is practically free from the risk of liberating free salicylic acid in the stomach.

Wide clinical experience anticipated these findings by demonstrating that "Alasil" can be pushed or prolonged to a much greater extent than ordinary salicylate compounds and that it can be given with safety to children, adults, the aged, and patients with finely-balanced digestive capacities. An analgesic, antipyretic, and sedative of established value.

A supply for clinical trial with full descriptive literature sent free on request.

SAFE AND CERTAIN BIOLOGICAL THERAPY

★ ANTIPEOL OINTMENT

The rapidity and efficacy of the treatment of skin troubles with ANTIPEOL OINTMENT is primarily due to its polyvalent antiviral content. Since various strains of streptococci, staphylococci and *B. pyocyaneus* are the root cause of nearly all the common infections of the skin (acne, eczema, boils, carbuncles, shingles, etc.), the destruction of those germs and the prevention of their further development is the first essential to healing. Antipeol destroys those germs biologically, without harming the tissues, and healing begins immediately. A test on an infected wound, burn, bedsore, or persistent ulcer will quickly prove the value of ANTIPEOL OINTMENT, and justify its use in any and every skin trouble.

The LIQUID FILTRATE is indicated for ear infections, suppurating wounds, septic cavities (dental and others) and inflammatory conditions. Used as a gargle with a little glycerine and water, ANTIPEOL LIQUID is both prophylactic and therapeutic for infective conditions of the throat.

★ GONO-ANTIPEOL

The antiviral treatment of Gonorrhoea and Genito-urinary infections is effective because it introduces and reproduces in the human body the antibodies of the gonococci, and reaches the remote sites of infection. GONO-ANTIPEOL contains the sterile vaccine filtrates of numerous strains of gonococci, as well as the streptococci, staphylococci and *B. pyocyaneus* common to gynaecological infections. It is thus a preventive of the development of germs, and aborts the disease when already contracted. Non-toxic, non-irritating, yet potently microbicide, GONO-ANTIPEOL is a perfectly safe, simple and effective therapy.

★ OPHTHALMO-ANTIPEOL

In addition to the antiviral of various strains of streptococci, staphylococci and *B. pyocyaneus*, OPHTHALMO-ANTIPEOL contains the autolysins of pneumococci Fraenkel and gonococci, since these micro-organisms are so frequently associated with eye troubles. The semifluid nature of OPHTHALMO-ANTIPEOL facilitates its dispersal over the affected area, and its soothing properties and efficacy are demonstrable from the first application. It is perfectly innocuous and may be used on babies.

★ RHINO-ANTIPEOL

The biological disinfection of the rhino-pharynx ensures antiseptis without the irritation associated with so many chemical disinfectants. RHINO-ANTIPEOL contains the antiviral and autolysins of the principal germs of naso-pharyngeal infections—staphylococci, streptococci, *B. pyocyaneus*, pneumococci, pneumobacilli, enterococci, *M. catarrhalis* and *B. Pfeiffer*—as well as calmate, de-congestive ingredients, ensuring a rapid clearing of the nasal passages. During epidemics of colds, influenza and diphtheria, RHINO-ANTIPEOL is the ideal prophylactic, and rapid relief follows its application in cases of Nasal Catarrh, Hay Fever, Coryza and other infections of the naso-pharynx.

★ ENTEROFAGOS (ORAL)

Nature's normal way of combating microbic infection is the production of antibodies (bacteriophages) capable of destroying the germs. ENTEROFAGOS is a combination of over a hundred strains of bacteriophages of the micro-organisms common to gastro-intestinal infections, and, when administered by mouth, immediately gets to the site of infection, and acts as a perfectly natural therapy. The intestinal troubles of early babyhood invariably respond to ENTEROFAGOS, as do seasonal diarrhoeas and the more serious dysenteric conditions of Typhoid and Paratyphoid fevers and Bacillary Dysentery. Certain major maladies trace their origin to intestinal infections, and the practical field of application of bacteriophage has by no means yet found its limit. ENTEROFAGOS is equally effective in the veterinary field, as greyhound and prize-cat owners have found to their joy, and the dreaded "white scour" in calves has no terrors when treated with ENTEROFAGOS. A non-irritant, innocuous medication administered by mouth, ENTEROFAGOS disinfects and immunises the digestive tract, and is more rapidly effective than vaccines, without the inherent disadvantages of the latter. A clinical test will prove these facts.

15 U.S.P. Units in each cc. of

1cc. Concentrated Solution Liver Extract (PARENTERAL)

Lederle

PREVIOUS CLAIMS for high potency per cubic centimeter of Lederle's "1 cc. Concentrated Solution Liver Extract Parenteral" have been established by the action of the U.S.P. Anti-Anæmia Preparations Advisory Board.

"1 cc. Concentrated Solution Liver Extract Lederle" has been tested in accordance with the methods described by the U.S.P. and it has been determined that 0.067 cc. per day for the test period produces the required hæmatopoietic response. Each 1 cc. vial of the extract, therefore, contains

15 U.S.P. UNITS

Advantages of "1 cc. Concentrated Solution Liver Extract (Parenteral) Lederle"

- a high degree of therapeutic effectiveness with a minimum of discomfort from each injection;
- rapid improvement in relapse;
- maintenance on a small number of injections;
- provides intensive therapy for those patients with extensive neurologic involvement.

Available only in boxes of 3—1 cc. vials, 14/5

MODERN COD LIVER OIL AS THE METHOD OF CHOICE FOR ADMINISTERING VITAMINS A and D

In view of the widely divergent opinions expressed concerning the dosage and vitamin content of various liver oils, the proprietors of 'SevenSeaS' cod liver oil wish to remind the medical profession that on January 1, 1936, the British Pharmacopoeia Commission laid down not only a definite dosage, but also a definite standard of vitamin content for cod liver oil.

The dosage was fixed at a minimum of 15 minims (a quarter teaspoonful) three times a day, and the vitamin content was standardised at not less than 600 International Units of Vitamin A and not less than 85 International Units of Vitamin D per gramme.

In 'SevenSeaS' Standard Oil, the practitioner has at hand a cod liver oil of the highest quality, fresh, easily digestible, and with a uniform vitamin content guaranteed to conform to the standard of the British Pharmacopoeia. The oil is rendered from the livers at sea as soon as the fish are caught (a process impossible with any other fish liver), instead of waiting until the ship is back in port and the livers consequently stale. The high quality of 'SevenSeaS' cod liver oil, and the uniformity of its vitamin content arising from its method of preparation, make it possible to prescribe only small doses which cannot give rise to acidosis.

These attributes are still further increased in the case of 'SevenSeaS' High Potency cod liver oil which is guaranteed to be four times as rich in vitamin values as the standard oil of the Pharmacopoeia. *With this oil available the practitioner who wishes to prescribe a particularly small dosage has the advantage of using a fresh cod liver oil without going far in excess of the standards laid down by the Pharmacopoeia regarding vitamin content.*

This High Potency Oil is not reinforced or in any way treated to increase the vitamin content. It is simply pure natural oil obtained by selection from the richest livers on the best fishing grounds.

All 'SevenSeaS' cod liver oil is tested and packed in strict conformity with British Pharmacopoeia requirements. Samples of the High Potency Oil, the Standard Oil, and the High Potency Oil in Capsules, will be supplied on request.

INDICATIONS FOR 'SANATOGEN'.

No. 15

THE CONVALESCENT

"The Need of Phosphates"

In convalescence from acute illness, perhaps the biggest problem confronting the doctor is that of diet and nutrition. Appetite, digestion and the absorptive faculties are all likely to be perverted; yet, at the same time, the provision of material for repairing and rebuilding the damaged and exhausted tissues is of first importance. There has generally been great protein waste, and obviously this must be made good. Carbohydrates are often metabolised with difficulty. There has nearly always been abnormal phosphorus elimination. It has been experimentally proved that in the formation of lactic acid from glycogen an essential intermediary is hexose diphosphate. Embden has shown that "muscle extracts incubated *in vitro* cannot form lactic acid from glucose, but can do so from hexose diphosphate"; the phosphate evidently acting as a catalyst. Moreover, for the building up of the lecithin, so essential a constituent of all cell protoplasm, an adequate supply of phosphate is necessary.

"I may say I have had excellent results from the use of 'SANATOGEN', and prescribe it extensively in convalescence after long illness, and in those cases where digestion is impaired."
—L.R.C.P., L.R.C.S.

"I have pleasure in telling you of my experience of 'SANATOGEN' in a case of debility following pneumonia. Once convalescence was established, the patient was put on 'SANATOGEN' for its food properties as well as its tonic properties. The patient was greatly emaciated; convalescence was slow, but the general appetite gradually improved, and I may say that I consider 'SANATOGEN' had a good deal to do with her complete recovery."
—M.B.

"I have given a trial to 'SANATOGEN' in a case of post-influenzal debility in a patient of 78. The result has been very satisfactory, and though debility has gone the patient still continues to take 'SANATOGEN' for its tonic effect. I am very pleased with the recovery in a woman of this age."
—M.D., D.P.H.

"I have used 'SANATOGEN' in my household, and find your preparation very reliable in toning up the nervous system in times of strain, and in convalescence."
—M.B., L.R.C.P.

Thus is partly explained the great value of 'SANATOGEN' during the convalescent period. 'SANATOGEN', containing 95% milk casein with 5% glycerophosphate of soda, is rapidly absorbed and utilised. It is non-irritative and, in addition to its high nutritive value, it stimulates gastric functioning, increases appetite and promotes the digestion and absorption of other foods taken with it.

'SANATOGEN'

(Trade Mark)

A brand of Casein and Sodium Glycerophosphate

Sold by all chemists price 2/3 to 19/9

DOSAGE: For children and adults two teaspoonsful three times daily, or according to circumstances. For infants $\frac{1}{2}$ teaspoonful added to each bottle feed.

The word 'SANATOGEN' is the Trade Mark of Genatosan Ltd., and is registered in the Trade Mark Office, London. It is a product of Casein and Sodium Glycerophosphate. A 'GENATOSAN' product made by GENATOSAN Ltd., Loughborough, Leicestershire.

Clinical samples and literature available on request to
GENATOSAN LTD., LOUGHBOROUGH, LEICESTERSHIRE

A major operation in progress in the operating theatre of a London hospital.

THE DANGER OF INFECTION

It is not only in the operating theatre that the value of antiseptic protection is to-day recognised. Men and women in everyday life are learning the importance of germ-free cleanliness. More careful attention to hygiene is resulting in better standards of health.

Of course, it is not possible in everyday hygiene for ordinary people to take such elaborate precautions against infection as those taken by the surgeon before an operation. Nevertheless, protective measures against the daily risks of infection are obviously needed, and it is generally accepted that the simplest and probably the most effective protection is that given by washing exposed parts of the body, such as the hands and face, regularly with a reliable antiseptic soap.

Wright's Coal Tar Soap has enjoyed the confidence of the medical profession for health protection for over 70 years. It has substantial antiseptic and anti-pruritic qualities, and is made from the costliest materials obtainable. It is the only soap in the world to contain 'liquor carbonis detergens' (Wright's), the valuable skin therapeutic recommended by leading dermatologists. An investigation by the Institute of Industrial Psychology reveals that more doctors themselves use Wright's than any other brand of toilet soap. You are safe in recommending Wright's to your patients—and in using it in your own practice.

WRIGHT'S
COAL TAR SOAP

Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics.

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of TAXOL, revert to normal and regular peristalsis.

In Gastro-Intestinal Disorders

Allenburys
BEEF JUICE

In such conditions it is a primary consideration that the food should be light and unirritating. In gastric and duodenal ulceration and in the dyspepsias, Allenburys Beef Juice may safely and advantageously be given, where beef tea would often increase the pain and have a harmful effect. Because of its high protein and vitamin content, it provides a valuable means of keeping up a patient's strength.

In bottles at 1/9 and 3/- each.

Descriptive literature and clinical trial sample will be sent on application.

ACUTE APPENDICITIS*

BY

G. GREY TURNER, M.S., F.R.C.S.

Professor of Surgery, University of London; Director of the Surgical Unit, British Postgraduate Medical School

"Let us return to our ideal; early operation is the only safe practice."—J. B. Murphy, 1916.

Since I was invited to take part in this discussion I have often wondered what induced the officers of the Section to choose this admittedly important subject. It appears to me that everything that can be said on appendicitis has already been much better said over and over again. Perhaps we are apt to forget that while the message is the same the audience is constantly changing.

It was Murphy of Chicago, one of the greatest teachers of all time, who declared that every few years important subjects in surgery should be reviewed and discussed so that the lessons connected with their management could be constantly kept before the profession. I am assuming that in discussing this matter we are but fulfilling this very proper idea.

Some time ago I was startled by the remark made by the husband of a very ill patient on whom I had operated for appendicitis with a complicating peritonitis, and who, unfortunately, succumbed. The man afterwards said how terribly disappointed he was, considering that his wife was only suffering from such a simple thing as appendicitis! I suppose it really means that as the great majority of the patients recover, when the result is otherwise everyone is surprised and disappointed. But, this being so, it shows how great is the responsibility laid on our shoulders. Yet in my view the real reason which justifies the discussion is because as a profession we cannot but be impressed by the individual tragedies to which we are unfortunately witness, and because we must feel in our heart of hearts that many of them might have been prevented.

Mortality Statistics

After all, appendicitis is not inherently a serious disease, though its potentialities for evil are great and alarming. The Registrar-General has very kindly supplied me with figures which show that about 3,000 people die every year from appendicitis in the United Kingdom. This number represents 12 per cent. of all the deaths from gastro-intestinal disease and 0.61 per cent. of the total deaths registered. Some may think this is not as high as might be expected, but at the same time, since we must know that it is largely preventable, it is somewhat of a reproach to our profession. In order to endeavour to discover the mortality of the surgical treatment of this disease I have been furnished with statistics covering a period of five years from two of our great hospitals—the London Hospital and the Royal Victoria Infirmary, Newcastle-on-Tyne. The figures are as follows:

TABLE I.—The Surgical Treatment of Appendicitis (Combined Figures for a Consecutive Five-year Period (1933-7) from the London Hospital and the Royal Victoria Infirmary, Newcastle-on-Tyne)

| | No. | Deaths |
|--|-------|-------------|
| Acute cases (excluding localized abscess) | 6,725 | 247 (3.67%) |
| Abscess cases | 604 | 51 (8.44%) |
| Above two groups (all acute cases) .. | 7,329 | 298 (4.07%) |
| All cases (acute, subacute, and interval) .. | 9,933 | 308 (3.10%) |

But I am not good at juggling with statistics, and I find that it is extremely difficult to get comparable figures from which one might draw perhaps some suggestive conclusions. I would, however, ask you to bear with me for a moment to consider some figures dealing with my own personal experience over the period of thirty-four years that I was in surgical practice in Newcastle-on-Tyne.

TABLE II.—Appendicitis to End of 1934 (Newcastle-on-Tyne)

| | No. of Cases | Deaths |
|---|--------------|------------|
| Group 1: Acute appendicitis without peritonitis .. | 159 | 0 |
| " 2: Acute appendicitis with localized peritonitis .. | 428 | 4 (0.93%) |
| " 3: Acute appendicitis with flank or pelvic peritonitis, or both | 230 | 22 (9.56%) |
| " 4: Acute appendicitis with diffuse peritonitis .. | 96 | 28 (29.2%) |
| " 5: Appendicitis with residual abscess | 64 | 5 (7.81%) |
| " 6: Appendicitis with primary localized abscess .. | 446 | 16 (3.59%) |
| " 7: Appendicitis—interval removals | 1,080 | 4 (0.37%) |
| " 8: Appendicitis with primary complications .. | 20 | 9 (45.00%) |
| " 9: Appendicitis—no operation | 0 | — |
| " 10: Appendicitis?—incidental removals | 0 | — |
| | 2,523 | 88 (3.49%) |

| | | |
|--|---------------------|---------|
| Groups 1 and 2 .. | 587 cases; 4 deaths | (0.68%) |
| Groups 1, 2, and 3 .. | 817 .. 26 .. | (3.18%) |
| Groups 1 to 6 and 8 (All acute cases) .. | 1,443 .. 84 .. | (5.82%) |
| All Groups .. | 2,523 .. 88 .. | (3.49%) |

The Classification of Appendicitis

So far as I am able to judge there can be no classification of appendicitis that is not open to error and to which objections cannot be raised. I can only suggest that the simple grouping employed has proved most useful. May I just point out that it is in no way selective and that, as it includes all the cases, anyone may draw their own conclusions from the information provided.

It will be noticed that the basis of the classification is a pathological one, for the disease starting in the appendix spreads from this area as a radiating infection. In the

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Plymouth, 1938.

great majority of cases appendicitis at its inception is a local disease, but when the infection spreads a secondary nidus arises in the peritoneum and in some cases in the blood stream. Group 5 includes those cases in which a more or less diffuse inflammation, as in Group 4, has fortuitously localized, but with abscess formation which is not necessarily around the appendix; it may be pelvic or subdiaphragmatic or in the flank. In Group 6, on the other hand, the inflammation has gone on to suppuration, but around the site of the appendix; wherever that organ may happen to be situated.

Group 8 comprises those cases in which there were primary complications—that is to say, in which patients have come under treatment suffering from appendicitis but with some such complication as acute intestinal obstruction, pyelophlebitis, advanced cardiac disease, pneumonia, or some other such condition. Group 9 was intended to include cases in which no operation was carried out, lest one might be accused of improving statistics by refusing to operate on bad risks. But the cases in which I have not operated have usually been those who refused surgical intervention, and these have been so few that years ago I ceased putting them in the table.

The heading "incidental removals" (Group 10) is included to give me the opportunity of saying that we ought not to count these cases in the statistics of appendicitis. If whenever the appendix is removed in the course of some other abdominal operation it is counted as an example of appendicitis, we can soon accumulate a very large series, but such a series can have no value so far as the problem of the treatment of appendicitis as an entity is concerned. The record goes back for many years, and includes those early days when I was formulating rules for my own guidance and learning technique. Many of those early operations were carried out in small industrial houses or country cottages.

If you will look at the figures you will see that the cases which reach the surgeon at an ideal stage—that is to say, while the inflammatory trouble is strictly limited to the appendix or in its immediate neighbourhood—can be operated upon with a mortality considerably less than 1 per cent. even in a reasonably large series like the 587 set out in Groups 1 and 2. But the extension of the infected process to the unprotected peritoneum, which brings the patients into Group 3, immediately introduces new factors which have a very serious bearing on the outlook. The involvement of the peritoneum in the pelvis, on the flank, or both, creates a new infective focus which may not readily subside as the result of removal of the appendix, with or without drainage. It is this group that furnishes a large proportion of the complications which provide such serious problems for treatment. These factors are reflected in the mortality, which in this group approaches 10 per cent. In these cases the infected fluid is free in the peritoneal cavity, and they might quite fairly be classed as examples of unlimited peritonitis, many of which are potentially general. But even accepting these considerations, if we add these cases to those in Groups 1 and 2 we get a series of 817, with a mortality of 3.18 per cent. The object of the classification, however, is to include all the cases so that we get a true picture of the mortality. If we do this and only exclude the cases operated upon in a quiescent interval we get a series of 1,443 cases, including that unhappy group where there are primary complications, with a mortality of not quite 6 per cent. But my chief point is that as a profession we must never be satisfied until we can manage to get

the great majority of cases treated by surgical means while they yet belong to Groups 1 and 2. If that could be done the experience of very many surgeons the world over shows that the mortality need not be more than 1 per cent. If this happy state can be brought about appendicitis might then be looked upon as the comparatively simple disease which it now is in the eyes of so many of the public. After all, the public look to us for guidance, and if it were universally insisted that very much better results would follow earlier intervention they would readily agree. To get the best results the co-operation of the public and of the profession is necessary.

In this matter of emergency surgery I do want to say what a great opportunity is presented in our large hospitals, or groups of hospitals like those under public authority control such as the L.C.C. or the Middlesex County Council. If agreement could be reached on a general classification which might be uniformly employed these hospitals could, in a few years, accumulate such a mass of statistics as would, let us hope, be useful in settling a good many problems which still remain unsolved. In this one respect we might take a lesson from Russia; I think it might be worth while. In their large emergency hospitals in Moscow they are trying out various methods of treatment checked by careful statistical records. It is a mass experiment which is extremely interesting, and may provide valuable guidance for the surgery of the immediate future.

Stage at which to Operate

In suggesting that the main consideration is the stage at which the operation is carried out, one can find a useful, though not entirely parallel, comparison in the treatment of ruptured peptic ulcer, for in that condition nothing makes so much difference as the time which elapses between perforation and the intervention. Here again may I just trouble you to look at some figures bearing on the matter and which speak for themselves.

TABLE III.—*Perforated Gastric and Duodenal Ulcers (Combined Figures of Mr. Grey Turner and Mr. Norman Hodgson to End of 1929)*

| No. of Hours of Perforation in 6-Hour Periods | No. of Cases | Recoveries | Deaths |
|---|--------------|------------|-------------|
| Up to 6 | 119 | 115 | 4 (3.36%) |
| 7 to 12 | 148 | 129 | 19 (12.83%) |
| 13 to 18 | 40 | 33 | 7 (17.5%) |
| 19 to 24 | 21 | 15 | 6 (28.57%) |
| Over 24 | 37 | 18 | 19 (51.35%) |
| Total | 365 | 310 | 55 (15.06%) |

All cases operated upon within twelve hours : 267 with 23 deaths (8.61%)

Why is it that so often surgery is not invoked while the disease is still limited to the appendix? I do not believe that the delay is so much due to mistaken diagnosis as it is to the expectation that the patient will get well without operative intervention. We all know that many sufferers do get well spontaneously, but at the same time I think we must admit that once the appendix has given trouble it is likely to do so again, and that it may be the cause of other troubles and is much better removed. Nevertheless, with the knowledge that many cases get well, it is perfectly reasonable that some patients, and often for the most excellent reasons, should wish to take the chance. But how are we to know that improvement is really taking place—what simple rule will guide us?

One of my former colleagues, the late Mr. W. G. Richardson of Newcastle-on-Tyne, to whom I am much indebted for many valuable lessons in emergency surgery, used to teach that in appendicitis it is unwise to conclude that natural recovery is taking place unless *all* the symptoms are improving. I have long been convinced of the great wisdom of this rule, and if it were always observed many a life would be saved and many a long illness prevented. It is not enough that pain is diminishing if the pulse is going up, or that the pulse remains unaltered if pain is becoming diffuse or the temperature is rising. The progress of the case is only sure if all the symptoms are simultaneously improving.

Early Diagnosis

How are we to make the early diagnosis which will justify the prompt surgical intervention which is so important? Well, there are easy cases and difficult cases, and nobody is more ready to admit that I have often been confronted with problems in diagnosis which only an operation has solved. In the easy cases—and they are in the great majority—the cardinal symptoms, as set out by Murphy, will always be found, and they are so important that I make no apology for referring to them once again. These are pain in the abdomen, which may be sudden and severe but is rarely overwhelming; nausea or vomiting or some gastric disturbance with disinclination for food; general abdominal sensitiveness, sooner or later more marked over the right side; and elevation of temperature. Murphy insisted that the symptoms occurred in that order, and was accustomed to say, "When that order varies I always question the diagnosis." But every case must be carefully considered, and I would say without hesitation that it is often indiscriminate diagnosis rather than hasty operation which brings early intervention into discredit.

The history of the onset is important; it may be sudden and severe, or more gradual. In the former case the patient may look very ill, and I have always attached importance to the testimony of those who know the patient and who can say that the aspect is altered. The rise in temperature may be slight, and Murphy used to point out that it may sometimes only be detected per rectum; but none the less I agree that it is never absent. It must surely be universally realized that the pain may be entirely epigastric or just around the umbilicus; but, wherever the pain, the tenderness is found only at the site of the appendix, and that is usually in the region of the right iliac fossa. In the presence of an acute appendicitis the pulse may be little affected; but as the condition develops it invariably quickens, and a steadily rising pulse is a valuable collateral sign. The condition of the tongue is seldom mentioned; yet it is invariably slightly altered even in the early stages, and, though difficult to describe, there is something about it that seems to me characteristic when associated with the abdominal sequence on which Murphy so much relied.

It was my friend Arthur Burgess who first impressed on me that it is not necessary to wait for rigidity before making the diagnosis. The mere difference in resistance as compared with some other part of the abdominal wall is enough to guide the experienced observer. This is especially valuable in the pelvic and retrocaecal cases, where the appendix is hidden away from the abdominal wall.

I would also emphasize that in appendicitis the tenderness is easily evoked by light palpation, and I am always gravely suspicious of the diagnosis in those cases in which it requires a deep and perhaps rather heavy palpation to elicit this sign. Murphy used to be very bitter about the

use of morphine in the treatment of suspected cases of appendicitis, and I well remember the cynical look on his face as he told his audience that patients so treated would recover in time to make excellent arrangements for their funeral! Rutherford Morison was equally emphatic, and used to tell us that if an abdominal pain was so severe as to require morphine for its relief then the case was one for operation. But in this matter my sympathies are entirely with the practitioner, for I know how insistent are the demands of the patient or the friends for relief. A single minimal dose of morphine may not mask the symptoms for too long, and as it wears off the return of pain is a certain sign of some grave condition, but the repeated small dose of morphine is fraught with great danger, and should never be employed when an abdominal emergency is in question.

It would go beyond the object I have in view to discuss the question of differential diagnosis, but there is one diagnosis that has certainly been responsible for many fatalities, and that is a diagnosis of abdominal influenza. I very much doubt if there is any such condition, and believe that it is usually only a handy explanation for some obscure inflammatory abdominal trouble, which in most instances has its origin in the appendix. From infancy to the age of 23 I myself suffered from numerous attacks which were confidently and repeatedly diagnosed as abdominal influenza but which were arrested for all time by the removal of a pathological appendix. But all cases have not so happy a sequel, and I could recount many tragedies due to this unfortunate diagnosis.

What can we do to help the young practitioner to recognize appendicitis at an early stage when operation is so insistent and so successful? Let us make more use of these common emergencies for teaching purposes. How often are we told on ward rounds that such and such a case is "only an appendix." These emergencies should be demonstrated to our students in all their aspects whenever the opportunity arises, and they should see the operations, watch the after-progress, and keep records of what are now looked upon as such ordinary conditions as to be scarcely worthy of notice.

Treatment in Early Cases

The treatment of the cases in this comparatively early stage is very simple, for all that is necessary is to remove the appendix and when in doubt to put in a small rubber tube to act as a drain.

"The state is best governed as you cook little fish, without much busyness."—Laotze.

It is perfectly true that there is often nothing to drain; but a small tube provides a track to the surface, and if the organisms do regain their activity after the removal of the offending organ such a track may mean an external discharge rather than an internal spread. At all events, I believe that a small tube properly placed often does good and never harm; but it should not be removed too soon, and I am accustomed to leave such tubes *in situ* for a week. If by that time there is no discharge they may safely be discarded. To the young surgeon I would most emphatically declare, when in doubt drain.

Complications of Peritonitis and Abscess

While, however, it is our plain duty as a profession to do everything possible to make an early diagnosis and to act upon it by prompt surgical intervention, one must admit that many patients are not seen until there are complications like peritonitis and abscess. Even in these circumstances I am convinced that they should be

regarded in terms of what relief may be provided by operation. But here I think we must be wise and recognize that some little delay may be an essential part of the management of the case and may be to the great advantage of the patient. For instance, in peritonitis where the abdomen is grossly distended, there is frequent vomiting, the pulse is quick, and there is obvious toxæmia it is essential to keep the case under observation for a few hours. During this time certain measures should be employed which may help the patient towards recovery by localization or so far improve matters that the necessary intervention may be carried out with more chance of success.

The stomach should be emptied by tube and the rectum by glycerin enema, while toxins are diluted by giving water by the bowel or intravenously. It usually greatly adds to the comfort of these patients, and I think may do some good, to apply heat to the abdomen, and during this period of preparation, the diagnosis having been made, a small dose of morphine may be extremely valuable. If, as sometimes happens, there is great improvement in the course of a few hours it may be wise to wait; but again the dictum of W. G. Richardson is to be the guide, and, unless all symptoms improve, then it is much wiser to make a small incision merely with the idea of giving exit to peritoneal exudate. In these circumstances a small incision or incisions under local anaesthesia, with the insertion of a tube, is all that is justified. The question of the removal of the appendix must be left to a later date. If, on the other hand, the patient arrives with clear indications of a localized abscess, convalescence will be aided and recovery helped by the evacuation of pus.

I have twice in my life seen patients with such an abscess die suddenly from rupture of the collection into the peritoneal cavity while waiting for absorption to occur, and many times I have seen the inflammation gradually spread and convert a local process into a diffuse peritonitis. In many cases of localized abscess it is possible to do a complete operation in the sense that the appendix is removed, but whether that is advisable or not must depend a good deal on the judgment, and especially the experience, of the operator. The life-saving measure is the evacuation of the pus, and for that a small incision with the insertion of a drainage tube is all that is necessary. The stage at which to re-intervene for removal of the appendix is a matter worthy of comment; but I do not want to go into that now, because it will sidetrack our discussion from its essentials. It is significant that in the large series of cases of appendicitis which I have quoted from London and from Newcastle-on-Tyne the localized abscesses (604) were attended with a mortality of something over 8 per cent. More difficult cases are that type in which the patient arrives with a very hard, localized, scarcely tender swelling in the iliac fossa. In such cases it usually means that the pus has already safely found its way into the bowel, which is a much more common event than its mere absorption, as I have repeatedly been able to demonstrate. If all is going well then, of course, it may be wiser to wait and to deal with the removal of the appendix as an interval operation; but again, unless all the symptoms are improving, I would have no hesitation in urging intervention.

The Late Stage

When can a case of appendicitis be said to be in a late stage? I have the greatest distrust of any rule in treatment which suggests that after a lapse of a certain

number of hours operation is inadvisable. I can never understand the rationale of such a dictum unless supported by an enormous mass of the most accurate statistical evidence. It rather suggests the Gilbertian situation that whereas at a quarter to twelve on one day the case ought to be operated upon, when that hour has struck it is already too late and the patient will have a better chance if treated by other means! Pathological processes do not attend on the clock, and whereas in one case diffusion of infection will have taken place within a few hours, in another this event may be delayed for days or may never occur.

Causes of Mortality

In endeavouring to evaluate the causes of the mortality I have been helped by my former assistant, Mr. A. Elliot-Smith, who has gone carefully into this matter in a considerable series of cases. His investigations tally with my own, to the effect that much of the mortality is due to complications. The main causes of death are undoubtedly an unarrested peritoneal infection, the formation of undetected abscesses in situations like the pelvis and the subdiaphragmatic areas, intestinal obstruction of various forms, cellulitis of the abdominal wall, and pulmonary infections. It is often suggested that the results of operations for appendicitis are largely influenced by the technique of the operator. This may have some bearing, but it is of very minor importance compared with the stage at which intervention is carried out. For instance, one operator, with certainly most excellent results, attributes a large part of his success to the fact that he never buries the stump of the appendix. I have always endeavoured to bury the stump, and I am equally satisfied that nothing but advantage has ever accrued to any of my patients from this step. I have lived too long in surgery to be influenced by the suggestion that any small detail of technique will alone make much difference in the mass results. All these things are of great interest, but I am equally certain that they are not essentials, and they must not be allowed to distract our attention from things that are.

I should be disloyal to my old school, however, if I did not once again urge the advantages of the oblique muscle-cutting incision of Rutherford Morison. For the early cases almost any type of incision will suffice, but for the later cases, and especially those presenting a lump, the oblique incision directly over the site of the mischief is much superior to any other. It has been a great satisfaction to me to find how readily my new associates at Hammersmith, who have all been trained in Southern schools, have appreciated the advantages of this approach. May I stress the importance of the careful closure of this incision in layers and with interrupted sutures of reliable stout catgut.

Treatment in Special Circumstances

There are certain circumstances in which acute appendicitis occurs which introduce special features that may have a bearing on its treatment. First of all in children, it is universally admitted that there are many pitfalls in diagnosis and that the disease may progress with alarming rapidity. To my mind this knowledge emphasizes the extreme importance of care in diagnosis in these little people. I want particularly to insist on the equal importance of following up a diagnosis of probable acute appendicitis by operation. Although we are all aware that diagnosis in children is difficult, in Newcastle-on-Tyne I was impressed by the great frequency with which

appendicitis was ultimately proved in cases in which our contributing doctors had sent the patients into the hospital with that diagnosis. In children the symptoms may vary rapidly, and many such cases appeared to have little the matter by the time they reached hospital, but when operated upon I nearly always found the appendix grossly and unmistakably diseased. Often the child will appear to be quite well and to have nothing but a little remaining tenderness over the appendix, and yet the appendix may be perforated and surrounded by pus.

In old people the peritoneum seems to lose its powers of natural resistance, and I am again satisfied that we should not postpone an operation because a patient probably suffering from appendicitis is aged. We should rather say that advancing age is a factor which prompts early operation. No one with any experience will overlook the fact that in the aged there are special difficulties in diagnosis: bowel growths, diverticulitis, and even prostatic mischief have not infrequently misled.

When appendicitis is a complication of pregnancy it demands early operation. The course of the pregnancy will seldom be interrupted by such intervention, and, in any event, whatever the risk so far as that is concerned, it is probably much less than the risk of a recrudescence of the disease nearer term, during labour, or immediately after. In my own experience I have only once had a patient abort, and I feel sure that was due to delayed intervention rather than to the actual intervention itself. The same applies to patients with heart disease, asthma, and pulmonary infections. In such cases local anaesthesia will often enable us to carry out life-saving operations with little anxiety.

I think we must admit that there may be a variation in the virulence of appendicitis, not only at different ages and in varying circumstances, but from time to time, depending perhaps on the seasonal variation in the organismal invasions of the gastro-intestinal tract. I was persuaded that in Northumberland there was some difference as between the country people leading a healthy open-air life and the town-dwellers, and I am quite prepared to hear that these differences are met with in other parts of the country. But these possibilities do not affect the general rule as to the necessity of prompt operative intervention.

The difficulty about all the plans which countenance delay in the surgical treatment of appendicitis is that they are apt to be abused, for the public and a certain section of the profession are only too ready to find an excuse for adopting any treatment other than operation. It is for this reason that I am afraid of any attempt at differentiation as between the cases which ought to be treated immediately by operation and those which may be left to a more convenient season.

Murphy used to deplore what he called "epidemics of so-called conservatism" in dealing with appendicitis, and I have myself often pointed out that the recurring advocacy of a waiting policy or delayed operation has almost invariably been followed by a wave of increased mortality.

Conclusion

Irrespective of interesting academic problems, I think it is essential that we should recognize that any acute condition of the appendix ought to be treated by operation without delay. I do hope that as the result of this discussion the message may once again go forth to the profession with no uncertain voice that appendicitis means operation, and that the earlier the operation the better the chance for the patient.

CARBOHYDRATE METABOLISM IN ANAESTHESIA: A REVIEW *

BY

R. R. MACINTOSH, M.A., M.D., F.R.C.S.

*Nuffield Professor of Anaesthetics, University of Oxford;
Anaesthetist, Radcliffe Infirmary, Oxford*

AND

C. L. G. PRATT, M.A., M.D., M.Sc.

Physiologist to the Department of Anaesthetics, University of Oxford

The production of surgical anaesthesia by the administration of ether or chloroform is accompanied by various metabolic changes, among which may be mentioned a rise of blood cholesterol (Reicher, 1908; Duceeseli, 1919; Mahler, 1926), a rise of blood fat (Bloor, 1914), increased blood phosphate (Marenzi and Gerschman, 1934), a diminution of blood potassium (Marenzi and Gerschman, 1932), interference with water metabolism, leading to dehydration of the bodies of nerve cells (Barbour, 1931), and disturbance of the acid-base ratio of the blood (Stehle and Bourne, 1924). More than all these, however, certain aspects of the alterations in carbohydrate metabolism have received attention from clinicians and from experimental investigators. Of such changes the most striking and the most widely discussed is the hyperglycaemia fairly constantly produced by some forms of anaesthesia.

Changes in the Blood Sugar.

That the administration of ether produces in the dog both hyperglycaemia and glycosuria was shown by Seelig (1905, 1906). Macleod (1913) stated that anaesthesia induced but slight changes in the blood glucose, and two years later Macleod and Pearee (1915) reported that ether actually produces a fall in blood sugar during the first half hour of ether narcosis. Ross and McGuigan (1915), however, measured the hyperglycaemia produced by ether and chloroform and, later, Ross and Davis (1921) attempted to distinguish between the mechanism whereby blood sugar is raised by the two drugs. Since then it seems to have been universally accepted that ether causes hyperglycaemia. Some observers—for example, Mahler (1926), Mackay (1928), Mackay and Dyke (1928), Minnitt (1932), and Hospers (1933)—have recorded considerable increases in the blood sugar level, sometimes to more than 200 mg. per 100 c.cm.; others, such as Nakamura (1935) and Hasaura (1935), have not detected such large hyperglycaemic responses; whilst Pratt (1938) found that the effect of ether upon the blood sugar level may vary considerably from case to case, generally producing a moderate increase, sometimes not influencing it, and occasionally even producing a fall.

Much less information is available as to the hyperglycaemic potencies of the newer or less common anaesthetic agents. Acetylene (Fuss and Deura, 1932), ethylene (Hospers, 1933), and nitrous oxide (Minnitt, 1932; Hospers, 1933) all raise the blood sugar level, but not to the same extent as does ether. According to Prasad and Sen (1936) sodium cvipan given intraperitoneally in the rabbit raises the blood sugar to a moderate degree, but the barbiturates, generally speaking (Heller and Nathan, 1933; Nakamura, 1935; Hasaura, 1935; Hrubetz and

* Read in the Section of Pharmacology, Therapeutics, and Anaesthetics at the Annual Meeting of the British Medical Association, Plymouth, 1938.

Blackberg, 1938), and avertin (Widenhorn, 1931; Nakamura, 1935) are thought to have little or no hyperglycaemic effect. It should be remembered, however, that the level of the blood sugar represents a dynamic equilibrium in which those factors tending to deplete it are balanced against those tending to replenish it, and that therefore the blood sugar level alone is not necessarily a simple or exact index of carbohydrate metabolism.

Action of Adrenaline

A good deal of experimental investigation has been directed towards discovering the mechanism of the production of hyperglycaemia by anaesthetic agents, and so many explanations have been offered that the subject has become confused rather than clarified. Shaffer (1914), for example, concluded that the partial asphyxia commonly produced during attempts to hurry induction was responsible, although King, Moyle, and Haupt (1912) had already shown that this could not be a complete explanation, because ether given intravenously also produces some degree of hyperglycaemia under conditions in which asphyxia is avoided. It is well known that asphyxia does cause hyperglycaemia—for example, Hospers (1933)—but it does not follow that hyperglycaemia must be due to asphyxia.

A more acceptable hypothesis which has gained some currency is that anaesthetic agents bring about the release of adrenaline into the blood stream from the suprarenal glands at an augmented rate, and that this increased concentration of adrenaline in turn accelerates the disintegration of liver glycogen, so mobilizing glucose. This is no doubt partly true (Browne and Evans, 1933; Vidal, 1933; Banerji and Reid, 1933), at any rate during the early stages of anaesthesia when excitation of the autonomic nervous system may be expected to occur. Nevertheless, Mekie (1931) found that in the rabbit the hyperglycaemia due to ether anaesthesia is not prevented by adrenalectomy or by the administration of ergotoxine or atropine. He concluded that the autonomic nervous system cannot be implicated and that the hyperglycaemia cannot be due to the mobilization of adrenaline. The evidence is, perhaps, not altogether conclusive, for atropine and ergotoxine do not entirely abolish all activity of the autonomic nervous system, and adrenaline may be mobilized elsewhere than in the suprarenal glands, but it is sufficient to emphasize the unproven nature of the hypothesis that anaesthetic hyperglycaemia is due in the first instance chiefly or altogether to the liberation of adrenaline.

Mobilization of Glucose from the Liver

The suggestion that anaesthetic agents mobilize glucose by a direct action on the liver has also been investigated experimentally. Linkoz (1926), for example, showed that various narcotics when perfused in moderate concentrations through the isolated frog's liver liberated glucose from that organ, and Fuss (1930) found that in the dog hepatic venous blood contains more glucose than portal venous blood during ether anaesthesia. Here again, however, matters cannot be regarded as settled. Ether and chloroform do not mobilize glucose from the isolated perfused liver of the dog (Ross, 1920) even when its glycogen content is normal. It has been claimed (Hrubetz and Blackberg, 1938) that the glycogenolytic power of the rabbit's liver is actually depressed by chloroform and various barbiturates, so that the hyperglycaemic effect of injected adrenaline is diminished. Mellanby (1919) concluded that since ether does not produce hyperglycaemia or glycosuria in the spinal animal its action

cannot be directly on the liver, but is in fact on the bulb. According to Tuckett (1910) ether produces an acceleration of glycogenolysis not necessarily confined to the liver.

Influence on the Action of Insulin

The question of the influence of anaesthetic drugs upon the action of insulin in the body has also been considered. Ross and Davis (1920) came to the conclusion that in the dog ether produces hyperglycaemia by hampering the action of insulin, but it has been shown (Chambers, Deuel, and Milhorat, 1927) that in the dog under amylal anaesthesia insulin has its usual hypoglycaemic effect, raising the respiratory quotient and increasing carbohydrate utilization as in the unanaesthetized animal. On the other hand, Aubertin and Trinquier (1933) concluded that chloralose actually enhances the effect of insulin in the dog. It may be stated that there is no indisputable evidence that anaesthetic agents interfere with the activity of insulin in the organism. The question as to whether anaesthetic drugs directly depress the pancreas and so diminish its output of insulin has not been adequately studied.

Depressant Action of Anaesthetic Agents

It is fairly well established that most anaesthetic agents diminish the uptake of glucose by the tissues, although whether this of itself could be responsible for the observed hyperglycaemia is very doubtful. This depressant action has been demonstrated by measuring the uptake of glucose from the surrounding solution by the unicellular organism *paramoecium* in the presence and absence of ether or chloroform (Estes and Burge, 1928). A similar effect may be shown indirectly for mammalian tissue: Amytal does not raise the blood sugar, but the glycosuria and hyperglycaemia produced by continuous intravenous transfusion of glucose in the dog are greater when amylal is given than in the unanaesthetized animal (Hines, Boyd, and Leese, 1926; Wierzechowski and Gadomska, 1927). This is good evidence that the ability of the tissues to utilize glucose is depressed even by amylal, although Lambie (1926), using the cat, concluded that ether and chloroform anaesthesia does not alter the rate of glucose uptake if the liver is excluded from the circulation. Hines, Leese, and Barer (1928) further showed that the increase of muscle glycogen produced by continuous intravenous transfusion of glucose is not affected by amylal, but that the increase in liver glycogen under these circumstances is halved by amylal anaesthesia. Fuss (1930) has also supplied evidence bearing on the relation of tissue glucose utilization to the hyperglycaemia of anaesthesia. He showed that in the phloridzinized dog ether does not raise the blood sugar, and deduced that the hyperglycaemia of ether anaesthesia is due to mobilization of glucose from the liver (rendered impossible, in phloridzin poisoning, by depleting the liver of glycogen) and not to any diminished utilization of glucose by the other tissues. Sansum and Woodyatt (1915) recorded a fall of blood sugar in phloridzinized dogs, brought about by ether and chloroform anaesthesia. Moreover, it has been shown that ether may not produce its customary rise of blood sugar in patients with hepatic disease (Canterow and Gehret, 1931).

Breakdown of Carbohydrate

The careful work of Uchida (1926), using the rat, demonstrated that various anaesthetics, including ether and chloroform, diminish the free carbohydrate in the brain to some extent and the total glycogen of the brain

to a much larger extent. Liver glycogen is certainly diminished during anaesthesia. The actual depletion has been measured in nitrous oxide anaesthesia (Browne and Evans, 1933), in amylal narcosis (Evans, Tsai, and Young, 1931), and in ether anaesthesia (Macleod and Pearce, 1910). Ether also diminishes the glycogen of the muscles (Major and Bollman, 1932).

There is thus good evidence that ether and at least some other anaesthetic agents accelerate the breakdown of glycogen in the brain, the liver, the muscles, and, no doubt, in all the tissues of the body. The mechanism whereby this universal glycogenolysis is set in motion is imperfectly understood, but it is probably safe to assert that the central nervous system is involved, and that any direct toxic peripheral action of the anaesthetic drug is prominent only in overdosage and is in any case a late effect. It has been suggested (Pratt, 1938) that the partial breakdown of carbohydrate metabolism may be due to some extent to interference not so much with glycogen itself as with some phosphorylated derivative such as hexose phosphate. This is supported by the observation of Stehle and Bourne (1924) that the acidosis of ether anaesthesia is due to the discharge of phosphoric acid from the tissues, where normally it is concerned with carbohydrate metabolism, into the blood stream. It may be that the hyperglycaemia of some forms of anaesthesia is a compensatory mechanism designed to minimize the effects of anoxia upon nervous tissue. It is known that the sensitivity of the central nervous system to anoxia is greatly increased by hypoglycaemia (Gellhorn, 1938), and that hypoglycaemia as well as anoxia depresses the rate of oxidation in the central nervous system. It is interesting to note that the intravenous injection of glucose in the dog may shorten the period of barbitol (veronal) anaesthesia by as much as 50 per cent. (Johnson, Luckhardt, and Lighthill, 1930). Although this effect was ascribed to diuresis, with an increased rate of elimination of the drug, some more specific action may be involved.

Effect on Metabolism

According to Inami (1931) the degree of metabolic disturbance in anaesthesia is proportional to the depth of anaesthesia. This has been confirmed (Pratt, 1938) as far as the hyperglycaemia of ether anaesthesia is concerned.

Anaesthetic agents have an even more intimate and probably much more important influence upon carbohydrate metabolism than any yet touched upon. It is generally agreed that the only oxidative metabolism carried on by nervous tissue is carbohydrate oxidation (Himwich and Nahum, 1932), and this peculiarity clearly renders nervous tissue specially susceptible to any agent which interferes with intermediate carbohydrate metabolism. Indeed, the opinion is steadily gaining ground that anaesthetic drugs may exert their specific effect by inhibiting some phase of the series of reactions involved in the oxidation of carbohydrate in nerve cells. Jowett (1938), using brain slices, has shown that various anaesthetics reversibly inhibit these reactions, and he has proposed to explain narcosis on that basis.

Conclusion

It may be permissible, in conclusion, in a paper that records so much of doubt and so little of certainty, to indulge in one further speculation. According to Mann, Tennenbaum and Quastel (1938), a precursor of acetylcholine exists in brain tissue. This "acetylcholine precursor" is synthesized when carbohydrate oxidation is

occurring, but is not formed under anaerobic conditions. Similarly, MacIntosh (1938) has recently shown that the production of acetylcholine and the transmission of impulses by the superior cervical ganglion is dependent, at least in part, upon the presence of glucose. It is an attractive hypothesis that anaesthetic drugs produce anaesthesia by diminishing the amount of available acetylcholine as a result of cessation or diminution of carbohydrate oxidation, and so preventing the transmission of impulses at synapses in the central nervous system. If this or some such mechanism should prove to be the case it would mean that at last we should have arrived at a theory of anaesthesia capable of being stated in current physiological terminology.

USE OF THE BACTERIOPHAGE IN AN
OUTBREAK OF INSTITUTIONAL
DYSENTERY

BY
DAVID HALER, M.B., B.S., D.C.P.
Pathologist to All Saints' Hospital and to the Battersea
General Hospital

Dysenteric infections in homes and hospitals for sick-children are common and very hard to control. These difficulties were accentuated in the outbreak here described, as it happened in a home for blind babies. It was inadvisable to close the home, and impossible, as will be explained, to secure effective isolation. In these circumstances treatment with bacteriophage was assiduously carried out in the hope that the infectivity of those affected might be reduced by some alteration in the bacteria, such as is supposed to be produced by the action of the bacteriophage upon micro-organisms. So successful does this appear to have been that the experience seems worthy of record.

The home had thirty-two blind children aged from a few months to 7 years. It is managed by a devoted matron, with a staff of eight skilled nurses, three teaching staff, and five domestics. All are under the regular medical supervision of an experienced local medical practitioner, with ready access to consultant advice. The medical officer is a regular visitor to the home.

The Cases

The first patient, on February 20, 1937, was hardly ill at all, although there was a little blood in the stools. This child was not suspected of having dysentery, and after a few days' segregation was allowed to join the other children freely. Whether there was a connexion between

this case and the epidemic that followed six weeks later is uncertain, but the child was again ill on April 22. On the latter occasion the first stool to be examined showed no dysentery bacilli, but on April 25 *B. dysenteriae* Sonne was obtained (Table I, Case 4).

Following this presumed first case, on February 20, there were three cases on April 4 and 5. Of these, two were mild and one moderately severe. The last-mentioned case passed blood and mucus, and from a specimen of the stool Dr. Selous isolated *B. dysenteriae* Sonne (Table I, Case 1). After an interval of four days there were four more cases on April 10 and 11. From the stools of two of these *B. dysenteriae* Sonne were obtained (Table I, Cases 2 and 3), and from the other two "atypical" dysentery bacilli—that is, Gram-negative, non-motile, non-lactose-fermenting bacteria, which fermented mannitol with the production of acid only, but did not, however, conform to any of the recognized dysentery strains: they failed to agglutinate with standard Oxford sera for the Sonne, Shiga, or Flexner groups. Three of these four cases were febrile and toxic, and a tendency to cyanosis was a feature of their condition.

A week later, April 18, another febrile case of dysentery occurred, and from this also *B. dysenteriae* Sonne were obtained (Table I, Case 3). On the 22nd the first case was again reported ill. This was a mild attack. The first stool examined gave a negative result, but from a stool on April 25 *B. dysenteriae* Sonne were obtained (Table I, Case 4). It is possible that this patient may have harboured *B. sonnei* from February 20 and thus have been the source of the other infections. Whence her infection came in the first instance could not be ascertained. On April 25 three more cases occurred (Table I, Cases 7, 9, 10). Two of these patients were nurses (Table I, Cases 9, 10), only slightly indisposed, but from them "atypical" dysentery bacilli were obtained. The accompanying chart conveys a clear idea of the pattern of the epidemic.

TABLE I.—Cases from which *B. dysenteriae* Sonne and/or "Atypical" Bacilli were Obtained

| Case No. | Date | Result of Stool Examination | Examined by |
|----------|---------|-----------------------------|-------------|
| 1 | 5/4/37 | Sonne present | Dr. Selous |
| | 2/5/37 | " | D.H. |
| | 7/5/37 | " | D.H. |
| | 20/5/37 | "Atypical" bacilli present | D.H. |
| | 27/5/37 | Negative for dysenteries | |
| 2 | 12/4/37 | Sonne present | Dr. Selous |
| | 25/4/37 | "Atypical" bacilli present | D.H. |
| | 7/5/37 | Sonne present | D.H. |
| | 24/6/37 | "Atypical" bacilli present | D.H. |
| | 7/7/37 | Negative for dysenteries | |
| 3 | 18/4/37 | Sonne present | Dr. Selous |
| | 4/5/37 | " | D.H. |
| | 19/5/37 | Negative | D.H. |
| 4 | 22/4/37 | Negative | Dr. Selous |
| | 25/4/37 | Sonne present | D.H. |
| | 14/5/37 | Negative | D.H. |
| 5 | 25/4/37 | Sonne present | D.H. |
| | 6/5/37 | Negative | D.H. |
| 6 | 25/4/37 | Negative | D.H. |
| | 6/5/37 | "Atypical" bacilli present | D.H. |
| | 7/7/37 | Negative | |
| 7 | 25/4/37 | "Atypical" bacilli present | D.H. |
| | 24/5/37 | " | D.H. |
| | 3/6/37 | " | D.H. |
| | 7/7/37 | Negative | |
| 8 | 25/4/37 | Sonne present | D.H. |
| | 10/5/37 | Negative | D.H. |
| 9 | 25/4/37 | "Atypical" bacilli present | D.H. |
| | 6/5/37 | Negative | D.H. |
| 10 | 25/4/37 | "Atypical" bacilli present | D.H. |
| | 6/5/37 | Negative | D.H. |

Chart showing a graphic representation of the epidemic

The Investigation

On April 25 I was consulted by Dr. Eric Pritchard, and was asked to investigate and to suggest a way of dealing with the outbreak. The home is situated in a very commodious and well-converted mansion, standing in its own extensive and attractive grounds. The appended sketch-plans of the two lower floors show the internal arrangements, and it will be seen how difficult was the problem of effective isolation in this epidemic. The water supply was from the town mains. There was no evidence of any epidemic in the rest of the area supplied. The milk was from local farms. It was not pasteurized, but was sterilized by boiling when received at the home.

These blind children are encouraged to lead as normal a life as possible. Vision, of course, plays a major part in the education of children; but in blind children this is perforce replaced by stimuli from touching, tasting, smelling, and hearing. It is desirable that they handle everything, and inevitable that they taste many things. Hence the control of an epidemic of a highly infective disease offers even more difficulties than those met with in institutions for more normal children.

Owing to the peculiar nature of the home there is no ward for the treatment and efficient isolation of cases of sporadic disease, and great reliance has to be placed upon "bed-isolation" (always a matter of difficulty, but more so in an institution of this kind).

Cases 9 and 10 were nurses, and were at no time really ill; they harboured "atypical" bacilli, and would never have been found had it not been possible to examine the stools of all the inmates and staff. Every case discovered at this time, with the exception of Case 11, was of the minor or carrier type, and in the ordinary course of events such cases would certainly have been overlooked.

There were then, on April 27, seven cases either known to have had dysentery or found on that date to harbour dysentery bacilli; one child negative on culture who subsequently developed the disease (Table I, Case 11); and two nurses (Cases 9, 10), who were shown to harbour "atypical" dysentery bacilli. The remainder of the children (twenty-two) were hitherto unaffected and presumably healthy. There were also seventeen nursing, teaching, and domestic staff. Efficient isolation seemed impossible without upsetting the routine of the home and thus nullifying much of the laborious and excellent work of the devoted staff, who were doing all that seemed possible to segregate the sick. It was

very undesirable to close the home and disperse the children to isolation hospitals.

Treatment

Accordingly I recommended that those who had been sick, those unaffected and therefore presumably at risk, and all the staff should receive one dose of a reliable anti-dysentery bacteriophage three times daily for a fortnight, and thereafter one dose daily. All those in bed and upon

bed-isolation received one dose of the bacteriophage three times daily until the stools were reported "free from *B. dysenteriae* Sonne, and from 'atypical' dysentery bacilli."

An examination of the stools of all the inmates and staff was begun. In the first batch of stools examined on April 25, 1937, there were thirty-six specimens—eighteen from child inmates and eighteen from the adult staff. Of this batch three were positive for *B. dysenteriae* Sonne and two showed "atypical" dysentery bacilli (these were the two nurses). The rest did not show dysentery organisms. On May 4 four more specimens were examined: of these only one showed *B. dysenteriae* Sonne. On May 7 eight more stools were examined and two showed *B. dysenteriae* Sonne. The examinations were continued at varying intervals until, at the end of the epidemic on July 7 a total of

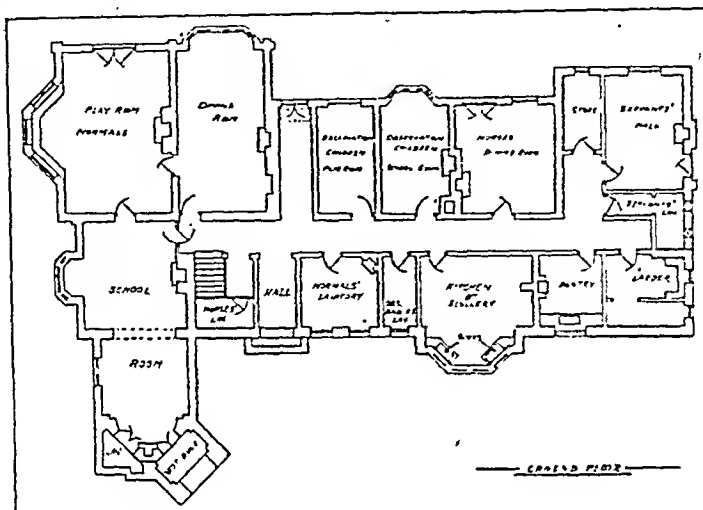

FIG. A.

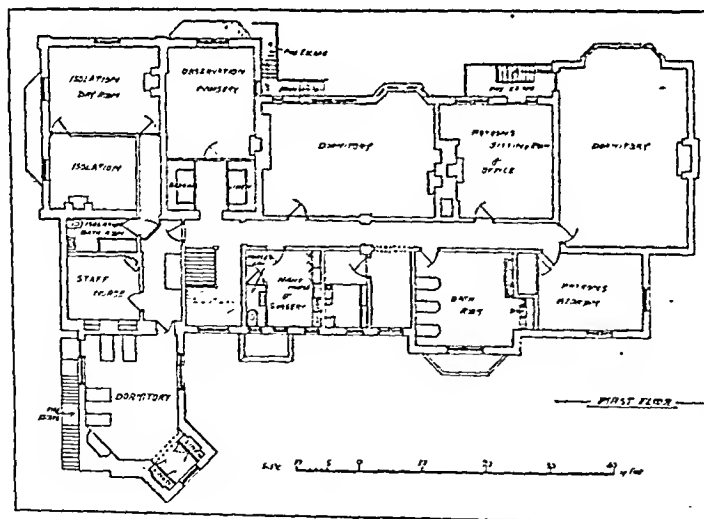

FIG. B.

sixty-six stools had been examined.

Bacteriophage treatment of the sick was started on April 25 and was extended to the whole institution on April 27. On the latter day, the second day after treatment was begun, one further case occurred. This was the last; and now, over a year later, there has been no fresh case.

This sudden cessation of the epidemic may have been a coincidence; but there was nothing to suggest that the cases between April 4 and 27 were being infected from

outside the home. The repeated findings of *B. dysenteriae* Sonne suggested that this infection was being spread. The "dropping" cases during the three weeks were what might be expected in an outbreak spread by contact infection; and even though the separation of the healthy from the sick was tightened up, the activity of these children, unbelievably quick in touching, smelling, and putting things into their mouths, made the transfer of infection probable.

The treatment aimed at the bacillus causing the disease: it sought by the action of the bacteriophage to modify the bacillus, and thus render it less capable of giving rise to dysenteric infection. Some modification did apparently occur, as towards the end of the epidemic there were more "atypical" bacilli and steadily fewer typical dysentery bacilli isolated. There was no change in the technique used, so it appears that the modification was truly in and of the bacilli. (It is open to argument whether "atypical" dysentery bacilli can be produced from pure strains of known dysentery organisms, but there is some evidence in the authorities which appears to support the proposition.) No medicinal treatment other than bacteriophage was administered. No case was removed from the home. Inquiries at the home at the end of April, 1938, elicited that no further case had occurred.

The bacteriophage was prepared at the Usher Institute of Public Health, Edinburgh. In its preparation races of bacteriophage active against strains of dysentery occurring in this country are largely used, and these include *B. dysenteriae* Sonne from a variety of sources.

I should like to express my thanks to Dr. Eric Pritchard for consulting me about this outbreak, for allowing me to use the bacteriophage treatment, and for his never-failing help and consideration in this and other matters; to Lieutenant-Colonel J. Morison, to whom I am indebted for the supply of bacteriophage, and much kindly help, advice, and friendly criticism; to Dr. W. E. Wallis, medical officer at the home, for his courteous assistance, for the efficient supervision of the outbreak, and for placing his records at my disposal; to the National Institute for the Blind for allowing the publication of this paper and for so readily supplying plans, documents, etc., relevant to this work; and, finally, to Mr. H. Clouston, my senior technician, for invaluable help in the isolation of the dysentery bacilli, and to the other members of my staff for their technical assistance.

"Problems of the Nations" will be discussed in a series of talks to be held in the Halls of City Livery Companies in aid of King Edward's Hospital Fund for London. The subjects will be "China" on October 6 in the Hall of the Vintners' Company; "Russia" on October 26 in the Hall of the Goldsmiths' Company; "Eire" on November 10 in the Hall of the Clothworkers' Company; and "Czechoslovakia" on November 24 in the Hall of the Drapers' Company. Ticket holders will be given an opportunity of seeing the premises and historical relics before the talks, which begin at 5.30 p.m. Further information and tickets (price 3s. 6d.) can be obtained from the Secretary, King Edward's Hospital Fund for London, 10, Old Jewry, E.C.2.

OBSERVATIONS ON THE POTENCY AND STABILITY OF DICK TEST TOXINS

BY

H. MASON LEETE, M.D.

City Hospital, Cottingham, Hull

J. McGARRITY, M.D. and F. L. KER, M.B.

City Hospital, Little Bromwich, Birmingham

AND

J. REID, M.D.

Lanark County Hospital, Motherwell

The Dick test is less reliable than the Schick test, and is therefore employed much less in clinical work. From time to time questions are asked about the possibility of improving the Dick toxin used clinically in many hospitals in this country. Is it of optimum potency at the time of preparation, and does the diluent ensure that undesirable deterioration does not occur before use?

We have recently been able to compare the potency of two toxins, one of which, Toxin A, was diluted in boric acid borate buffer solution (B.B.S.), and the other, Toxin B, in 0.4 per cent. phenol saline and in B.B.S. The former toxin is the preparation now used clinically by many workers in this country. We have taken the opportunity to inquire into the stability of the various reagents and also to endeavour to assess the error of the skin method of comparing two toxins in human subjects.

Reagents and Technical Details

The following toxin dilutions were available for injection:

1. Toxin A, diluted in B.B.S. 2 to 3 days previously
2. " " " " " 1 month
3. " B, " " " phenol saline 2 to 3 days previously
4. " " " " " 1 month
5. " " " " " B.B.S. 2 to 3 days previously
6. " " " " " 1 month

Dilutions 1, 3, and 5 were posted on the day of preparation, and dilutions 2, 4, and 6 had been kept at 4° C. for four weeks and were sent by post at the same time as dilutions 1, 3, and 5. The tests were made on the anterior surfaces of the forearms of Dick-positive individuals, separate syringes being used for each dilution. The sites of injection varied in different patients; thus a dilution might be injected on the forearm near the elbow in one patient and near the wrist in another. Readings were made after sixteen to twenty-four hours, the key to the order of injections being unknown to the persons making the readings. Throughout the investigation the greatest care was taken to exclude conscious and unconscious bias. The dimensions of the reactions were recorded in millimetres and notes made of their intensity.

Results

An analysis of the comparisons made at the different hospitals is shown in the table.

The following conclusions may be drawn:

1. Toxin A is considerably stronger than Toxin B.
2. Toxin A deteriorates slightly after four weeks in cold storage followed by two to three days at room temperature.
3. Toxin A which has been kept for one month is still considerably stronger than Toxin B freshly prepared.
4. Toxin B deteriorates slightly after four weeks in cold storage followed by two to three days at room temperature.

5. B.B.S. is a more suitable diluent than phenol saline for Toxin B. It ensures less deterioration after (a) two to three days at room temperature, and also after (b) four weeks at 4° C. followed by two to three days at room temperature.

Comparison of two Dick toxins, A and B, diluted in B.B.S. or 0.4 per cent. phenol saline (a) two to three days before injection, and (b) one month before injection

The toxins were supplied to the various hospitals in sealed glass phials and in rubber-stoppered bottles. There did not appear to be any significant difference between the results obtained with toxins from the two types of container, which were disregarded when the above table was compiled.

Discussion

From the combined research it is obvious that one has to use large numbers of persons in comparing the dilutions which were supplied of Dick toxins A and B. Discrepancies are apparent in an analysis of the data from different hospitals, and indicate the need for care in the interpretation of comparisons based on small groups. At the same time undue emphasis must not be placed on the discrepancies reported by different workers. Many of these were explained by a difference in measurement of a very few millimetres, as was evident from the original protocols (unpublished).

The influence of the diluents is also of interest. Boric acid borate buffer solution, which is now used in Great Britain, is a better stabilizing agent than phenol saline. A similar conclusion was reached by O'Brien, Okell, and Parish (1928), although in their early work a slightly higher concentration of phenol was used and a more rapid deterioration of toxin was observed. It is now well known that phenol is an unsuitable antiseptic for various other toxins—for example, diphtheria and tetanus—and for such immunizing agents as diphtheria prophylactic, A.P.T., which may lose its antigenicity rapidly in the presence of phenol.

A comparison of various Dick toxins has also been made by Ker (1937), who commented on the stability of the material used in his tests. His work emphasizes, too, the necessity for tests on a large group of persons in any investigation of this type.

With regard to the strength of Dick toxin used normally in our clinical work, the dramatic reduction of scarlet fever among nursing staffs after the introduction of the Dick test and active immunization indicates clearly that a

Dick-negative staff of nurses has a high degree of protection against infection; but we have seen a small number of relapses to Dick-positive and a few cases of scarlet fever among nurses who had formerly, or recently, been Dick-negative. On reviewing all the evidence, however, the results of immunization indicate that the Dick toxin used is of satisfactory potency.

Summary

1. In comparing two different samples of Dick toxin, tests on small groups of persons may be misleading. We would emphasize the need for making a considerable number of tests if an accurate result is required.

2. Boric acid borate buffer solution is a preferable diluent to 0.4 per cent. phenol saline, since it ensures greater stability.

3. The Dick toxin A, used normally in our clinical work, is of satisfactory potency and stability. Negative reactions with this toxin indicate a high degree of protection, although we have observed a few cases of scarlet fever in Dick-negative nurses.

We are indebted to Dr. R. A. O'Brien and Dr. H. J. Parish of the Wellcome Physiological Research Laboratories for the Dick toxins and diluents used for the tests.

A NOTE ON DIPHTHERIA IMMUNIZATION IN LONDON

BY

MAX SORSBY, L.M.S.S.A.

The increasing attention that is being paid by public health authorities to the immunization of children against diphtheria and the satisfactory results that have been obtained by various authorities in the reduction of the incidence of the disease by this procedure have led to the present study of the extent of diphtheria immunization in the child population of London. Diphtheria is a problem of no mean order in the metropolis. For the decennial period 1926-35 the following yearly averages for the County of London show the extent of morbidity and mortality.

| | |
|---|---------------------------------------|
| Approximate population (0-15 years) | 1,000,190 |
| Diphtheria cases | 9,047 (Attack rate of 9.04 per 1,000) |
| Deaths | 357 (Death rate of 3.65 per 10,000) |
| Case mortality, per cent. .. | 4.05 |

Immunization is carried out in the County of London mainly by the authorities of the different metropolitan boroughs. Holborn has provided facilities since 1922, and it was some years before other authorities followed: even now Bethnal Green has no local facilities, but makes arrangements for applicants to be immunized elsewhere. By reason of this lack of uniformity a much larger number of children are immunized in some parts of London than in others. Taking all the London boroughs together, by the end of 1935 there were 29,616 children potentially protected against diphtheria, either because of a natural immunity or as a result of immunity acquired by inoculation. The proportion of naturally immune children is not insignificant, for of nearly 30,000 no fewer than 4,698 were found Schick-negative at the primary test. On this basis something like 20

per cent. of the child population in London is naturally immune. It is generally agreed that for the diphtheria mortality rate to be tangibly affected at least 50 per cent. of the child population must be immune. There is therefore a wide gap to be bridged—one of at least 30 per cent. Thus, taking the figures up to 1935, it would appear that only a very small proportion of the child population has so far been artificially protected—actually not more than 2.3 per cent.

Recent Increase in Rate of Immunization

Since 1935 diphtheria immunization has been practised on an ever-increasing scale, so that this small percentage is no longer valid. In 1936 about 3,000 more children were protected, and whilst the figures for 1937 are not yet available, there can be no question that this number has been surpassed. As emphasizing the increasing rate at which immunization is being practised, it is worth pointing out that whilst in 1930 there were about 9,000 protected children, by the end of 1935 this figure was nearly trebled, and in the two years 1936-7 as many children were protected as in the preceding five years.

The L.C.C. has carried out immunization among the inmates of its institutions since 1932, and by the end of 1936 approximately 10,000 children had been successfully immunized. Adding these figures together, it would appear that at the present moment about 55,000 to 60,000 children in the London area have been actively protected, representing approximately 5 to 6 per cent. of the child population. If the 20 per cent. or so of the naturally immune children are added to this there remain about three-quarters of the child population not protected. In view of the risk run by the unprotected, an intensive effort towards popularizing immunization seems to be called for. The experience of Dublin, where, in the second half of 1935, 25,000 children were immunized, including 4,500 under school age, illustrates what can be achieved. In Chester about 45 per cent. of the child population and in Birmingham about 35 per cent. have been immunized. There does not appear to be any reason why other local authorities cannot do as well or even better.

The following table gives a detailed analysis of the extent of diphtheria immunization undertaken by the

COUNTY OF LONDON

Diphtheria Immunization. Totals to end of 1935

| Local Sanitary Authority | Approx. Average Population 0-15 Years 1926-35 | Date of Commencement of Immunization | Numbers Schick-negative at Primary Test | Numbers Given Full Course of Prophylactic | Numbers Fully Inoculated and Subsequently Schick-negative | Cases of Diphtheria Reported among Immunized | Diphtheria Attack Rate per 1,000 Immunized | Deaths from Diphtheria among Immunized Children | Total Known to be Protected (Immunized or Schick-negative at Primary Test) | Percentage of Known Protected to Total Population (0-15 Years to End of 1935) | Number Potentially Protected |

* No facilities for immunization yet in Bethnal Green. Applicants are referred to the Hospital for Sick Children, Great Ormond Street.

metropolitan boroughs up to 1935. It will be seen that in comparison with the general child population the incidence of diphtheria among immunized children is distinctly low (an attack rate of 1.77 per 1,000 immunized against 9.04 for the general child population) and that there has not been a single death from diphtheria in the forty-one cases occurring in the immunized group.

I am indebted to the Special Hospitals Department of the London County Council for the information contained in the table, and to Dr. G. H. Dart, medical officer of health for Hackney, for much helpful advice.

VASOMOTOR RHINORRHOEA, WITH ASTHMA, ASSOCIATED WITH MENSTRUATION

BY

A. S. HOSEASON, M.D., M.R.C.P.

Clinical Assistant in the Dietetic Department, lately Laking-Dakin Research Fellow, St. George's Hospital

The relation between nasal disorders and activity of the sexual organs, both in the male and in the female, was recognized by Hippocrates, Celsus, and Aristotle, and also in the Ayurveda, the ancient Hindu medical classic. J. N. Mackenzie (1884), an ear, nose, and throat surgeon of Baltimore, was the first writer of more modern times to make a systematic clinical study of this subject and to survey the literature. He observed in a certain number of women, whose nasal organs were otherwise healthy, that the nasal erectile tissue became congested at the time of the period, and even when the period was expected but happened temporarily to be suppressed. He said that his own experience was not great enough for him to say whether these changes also took place during pregnancy; but they have now, in fact, been seen to occur (Mortimer, Wright, and Collip, 1936a, 1936b, 1937). Moreover, the change is a steadily progressive one, with exacerbations when the periods would have been expected to be due but for the pregnancy. Mackenzie was of the opinion that nasal congestion was not confined only to women at the time of the periods, but that it might also occur during or after sexual activity in both sexes.

For fifty years the significance of Mackenzie's and other similar work has passed unnoticed and unexplained, but these clinical observations have now acquired a fresh significance in the light of recent advances in endocrinology, and are supported by a large body of experimental evidence, obtained mostly from work on monkeys (Mortimer *et al.*, 1936a, 1936b, 1937).

Hormonic Action on the Nasal Mucosa

Nasal turgescence is one of the "specific skin responses" to increase of circulating sex hormone occurring at oestrus. It can be provoked by injection of the appropriate oestrogenic hormones into male and female monkeys, including, as controls, those which are immature or castrate. Specific skin reactivity can be shown by simple transplantation experiments, where, for example, a piece of specific skin transplanted into a non-specific area still shows the specific response, and vice versa. Thus, non-specific skin transplanted into the perineal area of a monkey stands out as a "pale island

of skin in brilliantly coloured surroundings" (Bachman, Collip, and Selye, 1936).

This specific action of oestrogenic hormones on the nasal mucosa has been investigated and put to a therapeutic purpose by Collip and his co-workers in cases of atrophic rhinitis and ozaena. They observed much improvement after a course of local application of the hormones (oestrone or oestradiol in an oily solution). Incidentally, this series of cases showed an unusually high percentage of deafness and otosclerosis, which in a few cases responded to treatment, although otosclerosis is generally considered to be a most intractable cause of deafness.

The nasal congestion which is such a feature in the oestrous cycle of the higher primates has to a very large extent been lost in human phylogenetic development. None the less, it seems that the majority of women have some degree of nasal turgescence during menstruation and pregnancy. The bleeding of "vicarious menstruation" has been observed to come not from Kiesselbach's septal triangle, as is usually the case, but from the congested middle and inferior turbinates (Mortimer *et al.*, 1936b).

Many women complain that their noses are "stuffed up" or "run" immediately before or during their periods. In an unlucky few the turgescence may give rise to even more severe symptoms. In some women the nasal congestion may result in an attack of vasomotor rhinorrhoea; this is not an allergic reaction, but an exaggeration of a normal physiological response. Why this should be so one cannot explain; cellular pathology is even less understood than cellular physiology. "The reactivity of the tissues . . . is an important factor in determining the effects of hormone secretion" (Levy Simpson, 1938).

This type of vasomotor rhinorrhoea which occurs in association with the menstrual function might be termed "oestrogenic rhinorrhoea"; but this does not mean to say that an allergic factor is necessarily excluded. It usually occurs regularly about two days before the onset of the menstrual period, during which an attack of asthma may develop. The asthma is often slow in termination because, as frequently happens, a catarrhal bronchitis of bacterial origin may supervene. The whole illness is likely to take some time to resolve, only to recur with the next menstrual cycle. As this syndrome often first appears in children of school age who are taking their higher examinations, the resultant disability is serious. The patients are seen for treatment usually on account of their asthma only; the preceding rhinorrhoea, which is much less spectacular and disabling than the asthma, is either disregarded or self-diagnosed as a "cold in the nose." If this self-diagnosis is accepted as such and the asthma treated symptomatically, then the general prognosis as regards future attacks of asthma is not hopeful. But a careful questioning will reveal the true nature of the "cold"—that is, typical vasomotor rhinorrhoea, with no malaise or fever—and the prognosis is then materially altered.

Nasogenic Asthma

Asthma produced in this manner, by a nasal affection, is termed "nasogenic asthma," and its mechanism is reflex through the naso-pulmonary reflex arc. The control of bronchial calibre and the influence upon it of nasal stimulation has been studied with the bronchoscope in experimental animals and the reflex-paths worked out

(Maxwell Ellis, 1938). The existence of a similar control and influence in human beings is largely inferential from clinical observation, but there is also a certain amount of experimental support (Myers, 1929). The nasal element as the cause of an attack of asthma is not necessarily very obvious; the asthma may be preceded simply by a few sneezes or trivial nasal irritation, or running from the nose or eyes, the latter being a reflex via the sphenopalatine ganglion. In doubtful cases, when the patient is seen at the beginning of an attack of asthma, one may help to establish the diagnosis by spraying the interior of the nose with 2 per cent. cocaine solution, which may abort the attack by interrupting the naso-pulmonary reflex arc.

The simplest and most effective means of maintaining an interruption in the naso-pulmonary reflex arc is by the method of intranasal zinc ionization; this acts in much the same way as does the diagnostic cocaine spray. It is a non-specific method of rendering the nasal mucous membrane less sensitive to whatever may happen to be the sensitizing agents, and thus of interrupting unduly sensitive reflex arcs. The rationale and technique of intranasal zinc ionization has been dealt with fully and adequately by Shields (1936, 1937). He points out that the technique literally is an *intranasal* one, and that there are many possible sources of error. In some cases the sensitive areas may be high up in the nose and not entirely accessible by the ordinary gauze-packing technique. Ionization may then be carried out by continuous irrigation, as described by Shields (1937). Naturally it is essential to look for and attend to nasal or dental sepsis, or other well-recognized factors in the causation of asthma. In many cases also there may be easily detectable factors such as pollen or food susceptibility (Kennedy, 1936; Maxwell, 1936). Vasomotor rhinorrhoea is the outward sign of many possible inward disturbances, the nose being as it were a common denominator or "final common path."

Two Illustrative Cases

The following are two illustrative cases of menstrual asthma preceded by vasomotor rhinorrhoea which were sent to me as cases of simple asthma and which had previously been treated as such. It was decided to treat the apparent nasal origin of the asthma by the method of intranasal zinc ionization on the ground that it is effective in other cases of asthma caused by vasomotor rhinorrhoea, whether the latter is seasonal (hay-fever) or non-seasonal.

CASE I

A girl aged 14 was sent to see me on November 12, 1937. She was apparently normal physically, including the nasal mucosa. She had had a severe attack of asthma during her first period, and again with her second and third. Questioning elicited the fact that she had had a "cold" two days before each period, and further questioning made it obvious that the so-called cold was an attack of vasomotor rhinorrhoea. A first treatment by intranasal zinc ionization was given. She was seen again on November 19, and was menstruating, the period having come on a week earlier than was anticipated. She had had an attack of sneezing, with slight rhinorrhoea, on November 16, and the period had begun the following day, but there was no asthma. She was given second and third treatments on November 26 and December 10. The mother reported on January 3, 1938, that the girl had had no further symptoms. She again reported on May 20 that the patient was continuing well, and "had not had to stay away from school," but that there had been an insignificant running from the nose premenstrually. This latter observation may be

taken as reassuring from the point of view of the effects of the treatment, as it indicates that the nasal erectile tissue has not been destroyed and has not lost its capacity for responding to circulating oestrogenic hormones. If the mucosa returns to its previous more than normal responsiveness, then the treatment can be repeated. But this no more detracts from the value of the treatment as a method of controlling symptoms than does the necessity for repetition of injections in diabetes or pernicious anaemia.

CASE II

This is a rather more complex case, there being obvious dietary factors as well. A girl aged 16 was first seen by me on April 7, 1937. She had had asthma, preceded by "running colds," for two years since she had come to live by the sea. Inland she was well, except on one or two occasions. As a child she used to have severe urticaria after eating eggs or chocolate; when seen by me she was "upset" by milk and eggs during the attacks of asthma, but not in between. Her history showed that her asthma coincided with her periods and was preceded by vasomotor rhinorrhoea. On physical examination she was found to be normal with the exception of the turbinates, which were of a pale blue colour. The irregular rhythm of her asthma and the history of food susceptibility showed that there was more than one (oestrogenic) factor, but as the nose was the "final common path," and as she had had the usual treatment for asthma, it was decided to treat the nose. After a course of treatment by intranasal zinc ionization she had no more rhinorrhoea and consequently no more asthma. When last heard of, on May 31, 1938, she was still well.

One cannot disregard the possibility that this form of vasomotor rhinorrhoea, with or without asthma, may have some psychological basis, associated as it is with sexual manifestations. But in Case I the vasomotor rhinorrhoea preceded the patient's first period, the onset of which she obviously could not have anticipated. Further, in the two cases quoted the patients considered their "colds" as of no great inconvenience or disability; it is a universally recognized principle in psychology that the significance of a psychological symptom is in direct proportion to its value to the patient, and therefore this cannot be great if the owner of the symptom treats it as of not much importance.

I am greatly indebted to Professor Sir Walter Langdon-Brown and Professor Samson Wright for help and advice in the preparing of this communication and in the tracing of references.

The Autumn Exhibition of the Royal Institute of British Architects is to deal with the subject of the ordinary small house. It is to be opened jointly by Miss Ellen Wilkinson, M.P., and Mr. J. B. Priestley on Thursday, October 13. The object of the exhibition is to show ways in which the architects think the small house, provided for people of moderate means, might be improved. The exhibition will be open to the public, admission free, from October 14 to 29 at the R.I.B.A., 66, Portland Place, London, W.1. It will then, like all R.I.B.A. exhibitions, go on a tour of provincial centres and London suburbs for a period of two years.

Clinical Memoranda

Parental Whole Blood in the Prophylaxis of Measles

Reference to the literature shows that of the methods at present available for the prophylaxis of measles the injection of whole adult blood has been much less often employed than the alternatives: (a) convalescent serum, (b) pooled adult serum, (c) immune globulin prepared from placental extracts. This fact is greatly to be deprecated, because the use of parental blood at once commends itself as the most generally applicable, useful, convenient, and inexpensive method. The vast majority of cases in this country are treated at home by their family doctors, and for employment in these circumstances alternatives (a) and (b) are rarely available, while (c) is impracticable in most instances owing to its cost, and is not unlikely to meet with aesthetic objection from parents who may inquire into its source.

On the advice of the local medical officer of health, it was decided during an epidemic period, January to March, 1938, to adopt as a prophylactic method the injection of parents' whole blood into susceptible child contacts in the respective families, with a view to modifying the attack and avoiding complications in the secondary cases without sacrificing the permanent immunity to be derived from the attack. In domiciliary practice this is the obvious aim rather than complete prevention, which for various reasons may be greatly desired when measles is introduced to the children's ward of a hospital or into an institution. This method is particularly suitable to private medical practice, and affords an excellent opportunity for practitioners to make a real contribution to preventive medicine—an opportunity which should be seized before local authorities under pressure of public opinion are impelled to undertake measles prophylaxis during an epidemic.

TREATMENT

A series of twenty contacts were treated by injections of parental blood. The average quantity given was 10 c.c.m., which would be considered too little by most workers. A comparison of symptoms and signs both in these twenty secondary cases and in the eighteen original cases, which were familial, was made in detail. Contact was intimate in all cases, and the primary cases could therefore be taken to represent as nearly as possible a series of eighteen controls. The difficulties in the way of collecting a large series of cases appear obvious, but if the method were widely adopted valuable data would soon accumulate. The results in the present series were so gratifying that it is earnestly hoped that others will work on similar lines and publish theirs. The method is simplicity itself, the blood being withdrawn, with the usual precautions, from the father's (or mother's) arm and injected intramuscularly into the child's buttock. In no case was permission refused to carry out this procedure when the principle of the method was made clear; in fact the parents were delighted to co-operate in the treatment and were entirely satisfied with the results. In no case was there the slightest reaction to the injection, which caused little inconvenience. The use of parental blood, given intramuscularly, obviates the necessity for any special examination of it except in the case of parents suspected to be suffering from communicable disease, and eliminates reactions.

The epidemic was a mild one, the primary cases occurring chiefly among children 5 to 7 years old attending various

schools in Stretford. It is therefore considered that the infection in the control cases was fairly uniform; clinically the attacks certainly were, and it is felt that the primary cases may be compared to the treated cases, though, strictly speaking, they are not scientifically comparable in every respect. Such factors as time and intensity of infection are so uncertain as to render it impossible to obtain absolutely parallel control cases. Only one child contact in the practice was not treated by this method, and this child developed bronchopneumonia, from which she recovered. There were no complications either in the twenty controls (or untreated cases) or in the twenty treated cases. This was presumably due to the mildness of the epidemic.

The difficulty of estimating the exact day of exposure, and consequently the period after infection at which the blood was given, is obvious. Assuming that the rash shows on the fourth day after onset, it seems desirable to give the blood on the day following the appearance of the rash in the primary case.

In the present series the injections were given in six cases on the fifth day after first exposure (counting the day of the rash in primary cases as the fourth day of exposure of contacts); on the sixth day in four cases, on the seventh day in eight cases, and on the tenth day in two cases.

The amount of parent's blood injected was in two cases 5 c.c.m., in one case 7 c.c.m., in eleven cases 10 c.c.m., in one case 12 c.c.m., in two cases 15 c.c.m., and in three cases 20 c.c.m. It is considered that 20 c.c.m. of blood is a reasonable quantity to inject if circumstances permit.

RESULTS

Of the twenty contacts treated, four were completely protected, fourteen developed modified measles, and two were unaffected. One of the four who failed to develop measles was a boy aged 12, who may possibly have already acquired immunity, though there was no history of a previous attack. The two "failures" were: (1) a child of 12 who received only 5 c.c.m. of mother's blood, a totally inadequate quantity; and (2) a child aged 8 months who was teething and already had bronchitis before his measles began—he received 10 c.c.m. on the seventh day after exposure. The youngest patient, a baby of 3 months, gave one of the best results.

It is of interest to note that in two cases the parents were positive that they had never had measles, in one of these being supported by the contention of the grandmother. In two other cases the parents were doubtful as to their own history in relation to measles. As the results in these cases were good it may be supposed that a subclinical or undetected or undiagnosed attack had conferred immunity on the parents. In sixteen cases the blood was taken from parents with a definite history of measles in early life.

The eighteen primary cases were typical unmodified attacks of uncomplicated measles, with lacrimation, cough, rash, increased temperature and pulse, and bronchial catarrh. The fourteen contacts who developed modified attacks showed definitely less severe symptoms than the primary cases. Bronchial catarrh was entirely absent in every case, lacrimation appeared in only five cases, temperature and pulse were raised in nine cases, and slight cough was present in eleven cases. The rash in all fourteen cases was distinctly modified; in several cases only a few discrete blotches were discernible.

My thanks are due to Dr. A. W. Davison of Stretford for permission to publish this series of cases, and to Dr. E. H. Walker, medical officer of health for the borough of Stretford, for helpful guidance and advice on the public health aspects of the subject.

Manchester.

T. D. CULBERT, M.B., Ch.B.

The population of Japan in October, 1937, was 71,252,800. Of the 50,000 medical practitioners in Japan 2,000 are women, who were all educated at the Tokyo medical school founded in 1920. Only about ten possess the degree of doctor of medicine, which was first granted them in 1929.

Reviews

THE CHRONIC RHEUMATIC DISEASES

Chronic Rheumatic Diseases. Being the fourth annual report of the British Committee on Chronic Rheumatic Diseases, appointed by the Royal College of Physicians. Number Four. Edited by C. W. Buckley, M.D., F.R.C.P. (Pp. 160; illustrations; 5 plates. 10s. 6d. net.) London: H. K. Lewis and Co. 1938.

We welcome the fourth annual report of the British Committee on Chronic Rheumatic Diseases, which incidentally will be the last in its present form, since it has been decided to continue the reports in a biennial journal under the same editorship.

The present volume opens with a plea by Professor Stanley Davidson for Governmental organization to cope with the problem of chronic rheumatic disease, since in his view it is too big to be tackled by the voluntary hospitals of the country. Professor Hench gives us another review of the year's work in America. Gout is becoming more widely recognized, and even fibrositis, hitherto not held in much regard in the United States, is coming into its own. Hyperthermal treatment of gonorrhoeal rheumatism is proving more and more useful. Rheumatoid arthritis is still the centre of interest, if only because it is so very difficult to be definite about it. The magnitude of the problem—3,000,000 sufferers from arthritis—is at last beginning to stir the imagination of the American people.

Three chapters on sciatica are interesting chiefly because they show how the specialist tends to view a disease syndrome through his own tinted spectacles. The neurologist thinks only in terms of interstitial neuritis, the orthopaedist only in terms of strains, unbalance, and faulty posture involving muscles, ligaments, and joints. Dr. Kersley's chapter is the best as taking the most comprehensive view, but even he is inclined to be led away into the displaced nucleus pulposus, a clever invention of the surgeon to justify laminectomy, though it is difficult to see how constant pressure on a nerve fibre can help leading to early atrophy, and so a rapid cure of the symptom of pain by degeneration of the pain fibres. Sciatica will be better treated when patient and doctor are prepared to submit to those very difficult disciplines, patience and rest.

Mr. Mitchell contributes an interesting chapter on rheumatism in the horse, reminding us that we may learn much from comparative pathology. A note by Dr. Kersley on bone drilling in arthritis suggests that this is only likely to be useful in osteo-arthritis, and that further experience is necessary before it can be recommended. Thorium X as an example of radio-active substances has proved to be of no use in acute stages, but may be useful in the late chronic stages of rheumatoid cases. The evidence of virus infection in rheumatism is reviewed, but no conclusion can yet be reached. An interesting critical review of vaccine treatment is given by Dr. Warren. He concludes that vaccine therapy is valueless in acute rheumatic fever. In rheumatoid arthritis large doses are not useful but small doses may be helpful; further work with adequate controls is needed. There is no evidence that vaccine therapy is of any use in osteo-arthritis. Observations on the platelet counts during gold therapy are described, showing how easily these may reach a dangerously low level. At the St. John Clinic sixty cases divided into three groups were given large doses of gold, small doses of gold, and sterile oil as a control respectively. The first group showed the best clinical results, but there

were considerable toxic effects, means to avoid which must be discovered. Finally, Sir Leonard Hill describes the physiological action of some methods of physical treatment, showing how unfounded are some of the claims advanced, but also how useful some of these treatments may be.

All the contributions to this volume are interesting and valuable, but when published between stiff covers it may be that some readers will be inclined to regard them as more authoritative and final than they actually profess to be. Hence we commend the wisdom of the editorial committee in deciding to publish the essays in future as a journal. We wish this journal all success, and believe that it will be as valuable as the four annual volumes that have preceded it.

ANATOMY OF THE LIVING SUBJECT

Surface and Radiological Anatomy for Students and General Practitioners. By Arthur B. Appleton, M.A., M.D., William J. Hamilton, M.D., B.Ch., D.Sc., F.R.S.E., and Ivan C. C. Tchaperoff, M.A., M.D., B.Ch. D.M.R.E. (Pp. 311; 338 figures, including many in colour. 15s. net.) Cambridge: W. Heffer and Sons. 1938.

The authors of this book have reached out beyond the bounds of the descriptive anatomy of the dead "to the study of features that are accessible to examination in the living subject," which have become available by radiographic and other modern methods. They have attempted to fill a definite field and to bridge the gap in certain regions between the anatomy of the dissecting room and that of the living subject that has existed too long. There is a strong clinical flavour to this book—an obvious attempt to bring anatomy into closer association with the work of the clinician. The authors show how percussion, auscultation, the use of the laryngoscope, bronchoscope, gastroscope, and other instruments of clinical medicine may be employed to great advantage on fellow-students in the routine work of an anatomy department. The course of the nerves may be marked out by electrical stimulation, a method that can be employed also in the analysis of muscle action. In short, wherever possible, the authors have turned aside from the cadaver to the study of the living subject.

Concise orderliness is observed, descriptions are brief but adequate, and clearly the authors have restrained each other, with results that have made it possible to convey a vast amount of information in a volume of only 300 pages. It would, however, have been an advantage if references had been given, especially when it was obviously impossible for a subject to be adequately dealt with or receive more than passing mention. Throughout, the work is profusely illustrated by carefully selected radiographs, drawings, some of them in colour, and diagrams. Particularly successful are the photographs of various parts of the surface anatomy with parallel drawings of the underlying muscles, showing very clearly the nature and cause of the surface markings. We should imagine that artists would find these illustrations of great value, if indeed there are artists in these days who wish to represent what we ordinary mortals believe that we see. The standard of the reproduction of the radiographs is noteworthy, particularly in a volume that is turned out at so low a price.

The introductory section covers a wide range of subjects that are dealt with briefly, but on the whole satisfactorily. It is packed with useful information, much of which, though not definitely anatomical, is of interest and importance in the study of anatomy. We read of the possible variations that make the human being an individual and not a standard production. This aspect is stressed in a way that we have not noted in most works

on anatomy. Emphasis is laid on the group action of muscles and on their co-ordinated and antagonistic action—anatomy slides off into physiology. A brief outline is also included of all that it is necessary for the student to know of x rays in order to understand something of radiographic interpretation. A slight error is made when the authors state that "x rays are not perceived by the eye." X rays do affect the retina, but it was only the very early workers who tested this. To-day he would be a foolish person who subjected his eyes to a sufficient intensity of radiation to make this observation, which was at one time common knowledge. Nowadays protective measures are so adequate that practically no radiation comes to the observer.

The book is not divided into chapters but into sections that cover the usual subdivisions of "parts" that are dealt with in the dissecting room. Each section opens with a detailed description of the surface anatomy and works inwards towards the skeletal structures—the arrangement of the material is orderly and logical. In the past many have found difficulty in correlating the knowledge they acquired in the dissecting room with the conditions they met with in clinical medicine. To-day new methods are applied in the teaching of anatomy, and every attempt is made to "make the dead bones live." This volume, used in conjunction with the standard textbooks, will be of great assistance to students, and will appeal to all who have not had the advantage of learning their anatomy in schools where radiology and other accessory methods are employed.

HERNIA

Hernia: Anatomy, Etiology, Symptoms, Diagnosis, Differential Diagnosis, Prognosis and the Operative and Injection Treatment. By Leigh F. Watson, M.D. Second edition. (Pp. 591; 281 figures. 31s. 6d. net.) London: Henry Kimpton, 1938.

Dr. Leigh Watson tells us in the preface to a second edition of his book that the revision has been necessitated by the adoption by many surgeons of the treatment of hernia by injection, a procedure of the value of which he is convinced. In the fourteen years which have elapsed, however, since the first edition appeared there have been other changes in outlook and practice, and the work has been brought up to date to conform with these. The author states that at the present time the generally accepted cause of inguinal and femoral hernia is a pre-formed or congenital sac. We doubt, however, whether this would be conceded by many in regard to femoral hernia, but to support his contention he says that R. W. Murray made post-mortem examinations on 100 subjects who had no hernia during life and found twenty-one potential or empty sacs, all of which with one exception were of the femoral variety.

Each chapter is followed by a short bibliography, and a future edition would be improved by an index of authors in addition to the general index. No fewer than eight chapters of this edition are devoted to the injection treatment, which is considered in much detail. The work is well illustrated throughout. Dr. Watson apparently has not much faith in the inguinal sphincter, because even in children he reinforces the inguinal canal by a Bassini type of operation. Many who believe that even in young healthy adults suturing of the conjoined tendon destroys the action of the sphincter and that removal of the sac is all that is necessary or desirable would not be in agreement with him here. The rarer forms of hernia, such as sciatic, pudendal, and hernia through Petit's triangle, are described and illustrated, and there is a good account of intraperitoneal herniae. Left duodenal, as pointed out by

Lord Moynihan, is apparently commoner than right duodenal herniation and takes place into the para-duodenal fossa of Landzert, while right herniation occurs into the fossa of Waldeyer.

This continues to be a comprehensive and valuable work of reference, and, although the final chapter on medico-legal aspects will be chiefly of value to American surgeons, it contains much that will interest the reader in this country.

CLINICAL LECTURES ON PSYCHO-ANALYSIS

Clinical Aspects of Psycho-analysis. By Dr. René Laforgue. Translated from the French by Joan Hall. The International Psycho-analytical Library, edited by Ernest Jones. No. 31. (Pp. 300. 15s. net.) London: Hogarth Press, 1938.

This book consists of fourteen clinical lectures delivered to students of psycho-analysis. As such it cannot be and is not a systematic textbook for the beginner. But for those already acquainted with the teachings of the psycho-analytic school it contains many interesting discussions of difficult problems illustrated by case histories. There are chapters on the cure and completion of treatment illustrating the unwillingness of some patients to admit that they are cured and do not need to continue their visits to the analyst indefinitely. Again, on "active" treatment and the necessity to stimulate a desire to be cured the author is informative and interesting. In a chapter on the family neurosis he describes how neurotic parents may inevitably implant neuroses in their children and how these children react to the family situation. Finally the limitations of analytic treatment are discussed, and it is pointed out that the lives of some patients may be so utterly dependent on their illness, which serves them as a necessary protection or as a means of self-punishment for an overwhelming sense of guilt, that existence is insupportable without it. It is wiser, in the author's opinion, to leave such people alone.

The book has been well translated by Joan Hall, and is to be recommended to all those who are interested in mental mechanisms as interpreted by the pupils of Freud.

THE BROMPTON REPORTS

Brompton Hospital Reports. A collection of papers recently published from the Hospital. Volume VI. 1937. (Pp. 183; illustrated. 2s. 6d., postage 6d.) London: Research Department, Brompton Hospital.

Most of the papers contained in the sixth volume of these reports have already been published elsewhere by present or past members of the staff of the Brompton Hospital. To the following two papers special attention may be drawn. In "Pulmonary Tuberculosis in Young Adults: Significance of Contact History" W. E. Lloyd and Margaret Macpherson conclude that contact is an important factor in the aetiology of pulmonary tuberculosis in young adults and therefore that it should be possible to detect the disease in its early stages in many instances by examination of all those with a history of such contact. But the evidence they produce is, in the reviewer's opinion, not sufficient for concluding that it "stresses the value of continuing the observation of contacts for at least five years after they were known to be last exposed to infection." In "Chronic Diffuse Bronchopneumonia" J. G. Seadding describes a condition which he believes may be a recognizable clinical entity. He has since published further papers on this subject.

Three papers contained in this volume have not previously been published. F. H. Young and N. C. Oswald give an account of eleven cases of multiple cystic disease

of the lung. R. H. R. Besley gives a short study of the relationship of post-lobectomy atelectasis to bronchography, and W. D. W. Brooks and F. P. Lee Lander write on senile phthisis, the article being based on 364 cases, admitted between 1929 and 1935 to the Brompton Hospital, in which pulmonary tuberculosis apparently first produced symptoms after the patient had attained the age of fifty.

The volume concludes with the usual statistical hospital tables. The total number of thoraeoplasties performed (a thoraeoplasty in more than one stage is reckoned as the same number of operations) was 297. No fewer than forty-five lobectomies and ten pneumonectomies were carried out; and thirty-two operations for lung abscess. In the report of the pathological department we note with some surprise that, although a total of 1,064 examinations of the sputum for tubercle bacilli were carried out, there were only thirty-three examinations by concentration methods and only sixteen by culture. There is no record of examination of the gastric contents for tubercle bacilli.

Notes on Books

The third edition of E. T. BELL'S *Textbook of Pathology* (Henry Kimpton, 42s.) is larger than its predecessor by more than a hundred pages and contains many new illustrations. This work excels in terseness of statement, which enables a full description to be given in a small compass. The teaching is sound throughout and the sections on cardiac, arterial, and renal disease, which embody the statistical and other fruits of the author's own extensive studies, are particularly valuable. The arrangement is conventional, except that silicosis figures as a disturbance of pigment metabolism and deficiency diseases receive no separate consideration (in some cases none at all). Much recent work finds brief mention, but there is little discussion of controversial matters—perhaps a wise policy in a work intended primarily for the student.

Twelve teachers from medical schools in the Southern States of the U.S.A. have collaborated in writing Kracke's *Textbook of Clinical Pathology* (Baillière, Tindall and Cox, 27s.). This form of authorship, though suited to advanced treatises, is apt to lead in a textbook to lack of co-ordination. Of this there is evidence here both in repetition and omission: the chapter on the examination of faeces, for instance, is devoted almost exclusively to protozoa and parasites, and does not describe the test for occult blood or methods of bacterial cultivation. Methods of bacteriological diagnosis also receive scant attention in the chapters on urine and cerebrospinal fluid, and in that on sputum they are described only for the tubercle bacillus and the pneumococcus. Nearly half the book is devoted to methods of examining blood, and other subjects treated fully are the laboratory diagnosis of pregnancy, syphilis, and rabies. Most books such as this have their useful points in the form of new practical details or better illustrations, and with the latter this one is lavishly supplied. Most such books, and this is no exception, fail to cover so wide a field completely, and their practical use needs to be supplemented by reference to works on the individual branches of pathology whose application to diagnosis they describe.

In the section of Dr. Jurgens's symposium on rheumatism dealing with Bechterew's disease (*Die Bechterewsche Krankheit*) known to us as spondylitis ankylopoietica, Dr. WALTER KREBS considers that there is a primary weakness of the mesoderm, but that an infection entering by teeth or tonsils forms a metastatic focus which is responsible

for the actual syndrome, and that this is not influenced by subsequent treatment of the portals of entry. Occupation involving strain to the back may determine the incidence of the disease in a large number of cases. So far as diagnosis and treatment is concerned there is nothing particularly original, a survey of the usual methods being given. Dr. Wurm contributes a section on the pathological appearances in this disease. The book is published at Dresden and Leipzig by Theodor Steinkopff at RM.6.

Preparations and Appliances

HYSTERO-SALPINGOGRAPHY WITH A SELF-RETAINING INSTRUMENT

Dr. EDWARD ELKAN (London, W.1) writes:

The number of instruments invented for the performance of Rubin's test suggests that there is still room for improvement in their construction. The disadvantages of the available instruments are these:

The cone of the cannula has to be pressed firmly against the cervix, but where a spring is employed strong enough to prevent the reflux of the oil the procedure becomes too painful to be carried out without the aid of an anaesthetic. Where no spring is employed sufficient pressure cannot be exerted to prevent the reflux of most of the injection into the vagina. The cone itself, when round, does not fit well into the split external os of a multipara. A cone with an oval cross-section would not fit a multipara. Different cones are needed for both types of cases. The length of the uterine end of the cannula from the top of the cone to the end of the instrument is, in these instruments, unchangeable. The actual length of the cervical canal, however, plus the length of the cavum uteri is not the same in any two patients. The position of the cone on the cannula therefore should be made changeable, for it is important that the instrument should pass the internal os but not get in touch with the opposite wall of the cavum uteri. Where the cannula has a hole at the very end this can easily get obstructed. These holes should always be situated at the side of the tip of the cannula. To prevent the reflux of air in Rubin's test or that of oil in a salpingography, a vulsella is usually fixed to one side of the cervix. One vulsella can only exert an unequal pressure and cannot prevent the injection from escaping along the other side of the cervical canal. Furthermore, with an arrangement of this kind the oil can flow back freely as soon as the surgeon releases his hold on the instruments. If after an interval, during which the first radiographs are developed and viewed, the surgeon wishes to make a further injection, he will find the uterine cavity empty and the cannula out of position.

The instrument shown in Fig. 1 was evolved with the shortcomings of the available cannulas in mind. It has proved

Fig. 1.

useful to me and others and does not, at present, seem to need further improvement.

No spring is employed. The cervix is pressed against the cone by two vulsella forceps which are hooked on to the distal end of the cannula by means of an adaptable mount which carries the hooks. Each side is adaptable independently of the other. Two cones of different shape are supplied. They are interchangeable according to the shape of the cervix. The cone can be fixed anywhere on the cannula and the length of

the uterine end of the instrument is thus adaptable according to the length of the cervical canal and cavum uteri. The cannula is closed and blunt at the tip, the holes being situated a short distance from the end at the side of the instrument.

For the performance of either insufflation or salpingography the patient needs no preparation nor—with very rare exceptions—an anaesthetic. If an electric headlamp and a self-retaining vaginal speculum are employed the gynaecological

FIG. 2.—Case 2972. Tube and ampulla well filled on both sides.

FIG. 3.—Case 3107. Right tube normal; left tube blocked.

FIG. 4.—Case 3373. Right tube blocked. Oil escaping from abdominal os of left tube in small droplets.

part of the operation can be done without assistance. The steps of the procedure then are the following:

- Exposure of external os uteri with self-retaining speculum.
- Choice of cone according to the shape of the cervix.
- Insertion of vulsellum on right side of cervix.
- Sounding of width, depth, and direction of cervical canal and cavum uteri.
- Adjusting uterine end of cannula according to these findings.
- Insertion of second vulsellum opposite to first.
- Insertion of cannula.
- Passing the loops of both vulsella off the hooks of the slider.
- Adjusting the position of the slider on both sides so that sufficient pressure is maintained.
- Removing vaginal speculum.
- Supporting cannula and vulsella forceps with sandbags.

All this is done in a few minutes. We have now inserted a self-retaining uterine cannula which cannot change its position even if it is not held in place by anybody. The pressure applied to the cervix is evenly distributed to both sides. If narrowness of the vagina makes manipulation with two vulsella forceps difficult, one can be used. In this case the pressure applied to the cervix is, however, unevenly distributed and the cannula is not as well balanced as might seem desirable.

The opposite wall of the cavum uteri can neither be touched nor injured as the length of the intra-uterine end of the cannula was specially adapted for the particular case. The vaginal speculum, which causes two-thirds of the discomfort to the patient, is no longer needed after the cannula is in position, and can be removed. The presence of the remaining instruments is hardly felt by the patient, who can now slide back into any position suitable for the taking of the radiographs.

The patient can easily be screened while the opaque oil is injected, and the most suitable moment for the taking of the films can in this way be chosen. The oily base of the injection should not be too viscid. I find neo-hydriol more comfortable to inject than lipiodol, which, even if heated to body temperature, maintains a higher degree of viscosity. After the first one or two radiographs have been taken the tap of the cannula is closed and the syringe temporarily disconnected. The self-retaining instrument needs no further attention, and the patient can be left in the care of the nurse until the films have been viewed and a decision has been made as to the need of further pictures. Should these be found necessary more oil can be injected without delay: the patient experiences no discomfort through repeated adjustments and manipulations. After the last radiographs have been taken the instruments can be removed without reinsertion of the vaginal speculum. The patient all the time remains in the supine position.

I have to thank Dr. J. V. Sparks for his kind permission to publish these radiographs produced with the aid of the new instrument. The instrument itself was made for me by John Bell and Croyden, Wigmore Street, W.1.

HEPARIN

We have received samples of this physiological anticoagulant prepared for clinical use, both from British Drug Houses Ltd. and from Roche Products Ltd. The substance is prepared from liver, and its activity is measured biologically. The unit is the quantity required to prevent coagulation of 1 c.c.m. of blood, and the purified products contain 400–500 units per milligramme. Heparin is the most reliable anticoagulant to employ when taking blood samples, and it is probably superior to other anticoagulants for use in blood transfusions. Various workers have also reported favourably on the use of heparin in the prevention and the checking of the progress of venous thrombosis. The preparations have, therefore, a wide field of clinical use. British Drug Houses Ltd. supply sterile tubes for collection of blood which contain sufficient heparin to prevent coagulation. These will be a great convenience to practitioners.

ADRENALINE PREPARATION FOR ASTHMA

Vaporole solution of adrenaline (1 per cent.), issued by Burroughs Wellcome and Co., is intended for the symptomatic treatment of mild to moderate attacks of asthma. Graesser and Rowe (1935) showed that oral inhalation of a 1 in 100 solution of adrenaline produced in many cases a more rapid effect than did hypodermic injection of a 1 in 1,000 solution. The value of a technique which spares patients the inconvenience of hypodermic injections is obvious. In view of the potent action of adrenaline it is obviously important that the vaporole solution should not be confused with the usual 1 in 1,000 solution used for hypodermic injection. The bottles of vaporole solution and their containers are labelled "Caution—Not for injection," but we would suggest the advantage of making this warning somewhat more prominent.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 1 1938

THE PROFESSION AND THE EMERGENCY

Once again—and within twenty-five years—the members of the medical profession have had to share with all thoughtful fellow-citizens the anxiety of a worsening international situation and a menace of general European war. This time the black clouds have been longer gathering and the efforts to dispel them more protracted and persistent. With the causes of the crisis medical men and women as such are not directly concerned, save to deplore racial animosities that lie at the root of the trouble and to recognize some of the psychological factors in the background of political movements. Medicine knows no frontiers; so far from bearing any responsibility for international strife the medical profession has worked for harmony and appeasement between nations as between individuals. During these past weeks and days of growing apprehension doctors have gone about their daily tasks and steadied the nerve of others. If crisis should lead to catastrophe—and at the time of writing the issue of peace or war is still in the balance—they will continue at their accustomed duties, adding others to these as the national need demands. Their response to the call may be taken for granted, and those who have best prepared themselves beforehand will be of most service to the State. The British Medical Association long since co-operated with the Government in preparing a classified index of the members of the profession, for use in case of national emergency. The experience of 1914-19 proved that the medical profession can be trusted to organize itself efficiently in time of trial by machinery which interlocks with that of public administration both civil and military.

Let us hope and pray that medicine will not now have to mobilize for war; but the time has certainly come for bringing into action a strong and representative co-ordinating committee to give advice to the Ministry of Health and other Government Departments on the professional aspects of problems that would immediately arise if the worst happened. Among other questions that each individual doctor will ask is: "Where am I to go, and what am I expected to do in such and such circumstances?" The Central Emergency Committee, which was appointed by the British Medical Association at the behest of the Ministry of Health, already has definite functions. It has prepared a voluntary national register of medical

practitioners. It has been given the enormous task of advising the Government on the allocation and distribution of medical personnel. In this way round pegs will go into round holes. But that is not enough. There is need for a representative medical body which will undertake the larger task of advising the central and local authorities on the medical aspects of the many and complex problems that would immediately arise in the event of war. It needs little imagination to perceive that under present-day-war conditions practical steps will have to be taken, on behalf of the civilian community, which cannot prove effective without expert guidance from those whose duty it will be to give their service to the bodies and minds of the public.

Immediately the state of emergency arises, the Central Emergency Committee, with additions, becomes a Central Medical War Committee. As such it will deal with medical man-power. It could be given further powers and responsibility and become a body of a wide advisory and consultative nature. The Head Office of the British Medical Association has already issued to the secretaries of its units throughout the country a model scheme for the protection of practices of absentee general practitioners and a plan for setting up Emergency Medical Committees in every area. These bodies, at need, would function immediately as Local Medical War Committees in direct co-operation with the Central Medical War Committee for the general provision and allocation of medical personnel to the Defence Forces and for meeting all civilian medical requirements in the event of hostilities. Meanwhile the Ministry of Health has issued an announcement on the immediate duty of doctors and nurses, which will be found at page 719, with other information about measures to meet emergency.

ELECTRICAL INJURIES

The clinical and pathological pictures presented by cases of severe electrical injury are often so complicated that it has become imperative to reduce them; if possible, to their essentials from the point of view of the medical man faced with the problems of how to act in a given case. The characteristic electrical burn requires no special consideration other than that incident to the treatment of all severe burns. Much care is, however, necessary in deciding on a course of action in a case of apparent death from electrical shock, and for this some knowledge of the physiological and pathological effects of such shock is essential. In a recent publication Alexander¹ gives a critical review of the

¹ *J. Industr. Hyg.*, 1938, 20, 191.

literature on the clinical and pathological aspects. The minimum fatal current for human beings is from 70 to 80 milliamperes. If contact is sufficiently good and the duration of the current long enough 25 volts may be fatal. The resistance of the human body varies from 50,000 to 218 ohms according to the perfection of contact, duration of current, etc. In legal electrocution the contact is so perfected and the flow of current is so prolonged that the manifestations are not comparable to those found in accidental electrocution, where the contact is short in time and usually imperfect. Animal experiments have contributed much important information on the pathology of electrocution. It is found that in animals currents of low tension and intensity kill by producing ventricular fibrillation—closing the current inhibits the heart; opening the current is followed by fibrillation—and currents of high tension and intensity kill by paralyzing the bulbar respiratory centre. Direct experiment showed that cardiac inhibition is produced by electric shock (applied to the head) through stimulation of the vagus centre (cardio-inhibitory centre); cessation of the current is followed by a complete block at the vagus centre. Similar effects are demonstrable on the vasomotor centre; the current first produces a stimulation of the centre and then follows a temporary paralysis on cessation of the current—that is, intense vasoconstriction is followed by generalized vasodilatation, a state of affairs leading to stagnation of blood in the peripheral vessels on the venous side. The sequence of stimulation and later paralysis applies also to the respiratory centre. It was also found with animals that artificial respiration led to recovery in all cases in which no gross damage to the brain or spinal cord had been produced by heat effects.

Clinically, shock by currents of high amperage may produce unconsciousness for hours or days, beginning immediately after the shock; often there follows severe motor irritation (hyperkinesis or convulsions) associated with delirium and confusional states; the patient may be pallid or cyanosed; symptoms of raised intracranial pressure and cerebral oedema may supervene. It is not necessary for the production of these symptoms that the current shall have passed directly through the brain. Thus in a case in which the current passed from the right hand through the legs to the ground there was unconsciousness in a short time after the shock, and on recovery of consciousness there was vomiting, headache, monoplegia, and hyperaesthesia on the right side and the right disk was choked; the signs and symptoms cleared up in thirty-three days, and the neurologist in charge attributed the clinical picture to cerebral oedema.

Permanent disturbance of the central nervous system is not common, and when it occurs the symptoms resemble those of multiple sclerosis. Phenomena such as hemi-choreo-athetosis, myoclonus of the face, oculomotor and vestibular disorders, retrograde amnesia, atypical Parkinsonism, pupillary disturbances have all been described after severe electric shock. On the pathological side the principal changes found in the brains of patients dying in the acute stage of electrical injury are oedema and small perivascular haemorrhages. Where the current has passed through the head (as in legal electrocution) definite changes are found in the ganglion cells. In a fatal case described by Kawamura (quoted by Alexander) a young man of 26 sustained an accidental shock (A.C. 48 cycles, 220 volts) from his left hand to his left foot. The sequence of events was: the patient was first paralysed, then cried for help, and slid to the floor on being freed from contact; the pulse slowed and respiration gradually ceased, urine being voided. Post-mortem examination forty-six hours later showed meningeal and cerebral hyperaemia, pulmonary oedema, hepatic and renal congestion, perivascular haemorrhages, and congestion of cortex, pons, and medulla, and the blood in some congested vessels was homogenized (? hyaline thrombus). The question in this and in other similar cases is how to regard the brain lesions. The view of Jellinek is supported by Alexander that these lesions are secondary to the circulatory and respiratory inhibition, and that death is due to internal suffocation.

Emphasis must be placed on the fact that death from electric shock is not immediate but delayed and slow; the paralysis of the vital medullary centres is not permanent, and provided efforts to supply these centres with oxygen are successful, there is every probability of recovery. Alexander cites the remarkable series of cases published by MacLachlan in which of 479 cases of severe electric shock 323 were successfully resuscitated by the application of artificial respiration in a short time after the accident. Here it must be remembered that artificial respiration must be carried on, if necessary, eight to twelve hours by shifts of trained men until either spontaneous respiration is established or livid patches and rigor mortis appear. The importance of this procedure cannot be too strongly stressed, since post-mortem examination has shown that persons have "lived" after the accident for periods much greater than has been suspected. Intracardial injection of atropine and adrenaline is a valuable aid, and if after recovery there is evidence of raised intracardial pressure lumbar puncture should be carried out and repeated if necessary.

PROGRESS IN RADIUM THERAPY

The Annual Report of the Radium Institute for 1937, which has just been published, is the last which will appear under that title. The amalgamation of the Institute with the Mount Vernon Hospital has now been completed, and in future the work of the two institutions will be performed by a single body—the Radium Institute and Mount Vernon Hospital. During the past year research into radium beam therapy has been continued; in addition to providing accommodation for the two five-gramme units the Institute also supplies some of the necessary staff, maintains thirteen beds reserved for patients undergoing this form of treatment, and bears the cost of overhead charges. The importance of research into the treatment of cancer by massive units is great from the point both of exploring therapeutic possibilities and of investigating the best conditions of safe working for patients and operators. In the general medical part of the report, contributed by Dr. Roy Ward and Dr. Durden Smith, one of the questions considered is that of the possible invasion of the urinary bladder in cancer of the cervix uteri. Subsequent experience has confirmed the view expressed in 1935 that micturition symptoms and bimanual examination are insufficient and unreliable as affording evidence of involvement of the bladder. It was suggested then that gross vascular dilatation and petechiae shown by cystoscopy at the base of the bladder might be of prognostic significance. The suggestion was made on the ground that two patients with early cervical carcinoma in whom these signs were present died with extensive neoplastic infiltration of the bladder in the second year after treatment. Routine cystoscopic examinations of a further hundred cases have, however, demonstrated that no such special significance can be attached to these appearances. It had also been regarded as probable that when cystoscopy showed definite invasion of the bladder treatment should only be local and palliative; it is now considered advisable that the full treatment should be given. Recurrences after Wertheim's operation have shown that of eighty patients given radiation therapy between 1925 and 1932 ten survived five years and over; of the remainder twelve were untraced and one died from other causes. Since 1932 five more patients—of whom three are still alive—were treated either by vaginal irradiation alone or by vaginal irradiation combined with interstitial radium to a recurrent mass, carried out per vaginam. There is an interesting note on "pitch warts," which are common in those who work with gas-tar and the various oils derived from the destructive distillation of coal. With the exception of the scrotum, these warts occur on exposed parts of the body—the face, neck, scalp, forearms, and hands. Many workers, however, who have been employed in these industries for fifteen years or more show no signs of developing any such lesion. It is, nevertheless, evident that in many cases the process begins long before there are any clinical manifestations, since pitch warts are seen in patients who have discontinued working with coal-tar and its products

for several months or even years. There are two main clinical types. The one is soft, villous, and easily bleeding; while the other, and commoner, type is hard, smooth, and rounded and can be detected on palpation before any lesion is visible. In their later stages they appear as conical warts with the superficial layers of the skin stretched over them, and ulceration, if it occurs, affects only the apex. Their importance lies in the fact that if neglected they are very likely to become carcinomatous. Fortunately, they are extremely radiosensitive: treatment is by unscreened radium plaques placed in contact with the wart for periods of from one hour and twenty minutes to one hour and forty minutes, and they nearly always disappear in from four to five weeks. Increased care by employers and improved education of workers have considerably diminished their frequency in recent years. The report includes an account of twenty-eight cases of limbal tumours—growths arising from the junction of the cornea and conjunctiva—most of which were squamous-celled epitheliomata. These were treated by unscreened radium plaques placed in contact with the growth, and no instance of cataract was recorded. In all but two cases, in which enucleation was subsequently performed, the results were completely satisfactory. It is to be hoped that these cases will be kept under careful observation, as they afford excellent material for observing any possible subsequent effects of radiation upon the retina. The statement is frequently repeated that nerve cells of all kinds are practically immune from injury by radiation, but recent investigations have shown marked histological changes. The Radium Institute has here a valuable series of cases treated under identical conditions in which periodical ophthalmic examination may give information of practical as well as of scientific interest.

THE PRAGUE SERA REACTIONS FOR CANCER

Professor Heyrovsky has recently summarized¹ investigations carried out in the Charles University of Prague on the diagnosis of cancer by his polarographic method, a more detailed account of which was published earlier by Brdicka.² The method consists in measuring the direct current passing at increasing voltages through a fluid between electrodes of special type. The apparatus used records the current-voltage curve photographically. For the diagnostic test 0.2 c.cm., or even less of serum, is subjected to a short and simple chemical treatment and then examined by the polarograph. A positive reaction is shown by a characteristic change in the current-voltage curve. Brdicka reports tests on sera from 187 individuals. The polarographic diagnosis was correct in 113 out of 120 patients with malignant disease, while among thirty-eight normal sera only one gave a positive reaction. Nevertheless, the test is not specific for cancer since positive reactions are obtained in febrile and inflammatory conditions. Tests made in Copenhagen by Bergh, Henriques, and Shousboe³ gave similar

¹ *Nature*, 1938, August 20, 317.

² *Act. Unio Internat. Canc.*, 1938, 1, 13.

³ *Nature*, 1938, April 23, 751.

results, though positive reactions were recorded for patients with hepatic disorders. The Danish workers state that the difference between non-cancer and cancer sera is unquestionable, but they are not yet prepared to assess the diagnostic value of the reactions or to decide what constituent of serum is responsible for them.¹ Brdicka ascribes them to an increase in protein cleavage products due to the abnormal proteolysis of albumins. Investigations are in progress to determine whether the cleavage products are the same in cancer patients as in febrile patients; if not, an important refinement of the test will be possible. Some indications that the reactions vary quantitatively with the stage of cancer development are also under examination. Diagnostic tests for cancer have a poor record. Dr. P. N. Pantoni² reported unfavourably on several and found an important cause of exaggerated claims in the inadequacy of clinical control. But, as he says, the problems of early diagnosis and treatment are so important that claims to solve them cannot be rejected out of hand because the underlying theories are improbable. It is reasonable, therefore, to withhold judgment on the Prague reactions but to admit that they deserve rigorously controlled investigation. They have received a measure of independent confirmation which seems to justify the claim that the results are perfectly reproducible, and it is noteworthy that the chemical treatment is simple and that the reactions are registered automatically. Thus there are grounds for hope that this test, unlike some others, will not be dependent on the meticulous performance of ill-defined but involved technical procedures nor upon uncommon skill and ingenuity on the part of the investigator.

A CONVENTION ON OPIUM PRODUCTION

The Advisory Committee of the League of Nations has now formulated, and submitted to the Governments concerned for their observations, the main principles on which a new opium convention might be based. The objectives defined are (1) to suppress the abuse of narcotic drugs, (2) to supplement the Hague Convention of 1912, the Geneva Convention of 1925, and the Narcotics Limitation Convention of 1931. To these ends the production of raw opium is to be limited to recognized world requirements, and a definite quantitative limit is to be fixed annually. An international controlling authority is to allocate to each country, on the basis of estimates furnished by them, the quantities annually to be produced, exported, or imported, as the case may be. Stocks of raw opium are to be regulated alike in producing and in consuming countries. National control will also have to be provided for in harmony with the international scheme. The substances to be covered by the future convention on production are:—(a) Subject to limitation: (1) poppy cultivated for the production of raw opium; (2) raw opium. (b) Subject to certain measures of control: (1) poppy plant, if and when used as raw material for extraction of opium alkaloids;

(2) opium poppy cultivated for other purposes. The amount to which production of raw opium is to be limited is to include, besides that for medical and scientific needs, what is required for making "prepared opium" for smoking so long as its suppression is unachieved, and for "non-medical internal consumption at present authorized in certain countries." This last reservation is presumably intended to cover the case of India, where it has been officially contended that the non-medical consumption—for example, eating—of opium or its employment as a household remedy will be provided for. Much discussion took place over the use of the poppy plant as raw material for the extraction of opium alkaloids, notably as practised in Hungary and Poland. It is stated that in 1936 some 1,400 kilogrammes of morphine were extracted from poppy straw. The question of how to deal with this problem—whether under the Limitation Convention of 1931 or in the same way as it is proposed to deal with raw opium under the new convention—appears to have been left an open question. Another matter which remains at present undetermined is as to whether there should be limitation of the area to be cultivated under the poppy as well as the limitation of the actual production of raw opium. Finally, it was pointed out that the future convention could not operate successfully unless it received practically world-wide application. The representatives of Turkey and Yugoslavia declared that their Governments would be unable to adhere to a convention which was not ratified by all the principal producing countries.

INTRAVENOUS SEDATIVES IN PEPTIC ULCER

Efforts to find additional aids to the treatment of chronic peptic ulcer in the form of parenteral injections continue to be made. One such attempt recently reported by Daprà and Silvani¹ utilizes an old and well-tried friend in treatment—namely, sodium bromide. Their method, which was tried in eight cases, seems to be based on that described some twelve months ago by Landau and Hejman.² It consists of a series of intravenous injections of 10 c.cm. of a 10 per cent. solution of sodium bromide, together with 1 mg. of atropine sulphate. Atropine in sufficient dosage has a depressant effect upon vagus excitability and reduces the gastric acid secretion; it has long been used either orally or subcutaneously, and holds a definite place in the treatment of ulcer. Sedatives acting mainly upon the higher centres appear to have been less widely tried, though there can be no doubt as to the importance of emotional and nervous factors in the natural history of peptic ulcer. At the same time the experience of most observers has been that orally such simple sedatives as the bromides or the barbitones are often ineffective in relieving symptoms unless they are given in large doses; where relief of symptoms demand a sedative opium or one of its alkaloids is more usually needed and for short periods is often of the greatest assistance. On

² *Presse méd.*, 1937, 45, 1468.

a priori grounds it would therefore seem unlikely that some 15 grains of bromide injected intravenously would act very differently in aiding the healing of peptic ulcer from an effective dose of, say, morphine given subcutaneously. The exponents of this form of treatment suggest that the depression of the central nervous system by the bromide and of the vagus by the atropine breaks a "vicious circle," so that the "equilibrium of the vegetative nervous system is restored" and healing may begin. Such a rationale and such a form of treatment demands an extensive and adequately prolonged study of a number of cases before it can be judged, in the words of Landau and Hejman, as "certainly marking a progress in the conservative treatment" of ulcer. These authors report three cases of chronic peptic ulcer, in one of which there was practically complete disappearance of an ulcer niche radiographically—after forty-nine injections! In all three patients symptoms quickly or gradually subsided, the observation periods being of some weeks' or months' duration. Conditions such as peptic ulcer in which periodic relapse and remission is the rule require prolonged periods of observation before the effect of treatment can be assessed. In few diseases can the *post hoc propter hoc* argument be less fairly applied.

CERTIFICATION OF THE CAUSE OF DEATH

Dr. A. Hardisty Sellers of the Department of Health for Ontario has recently published an excellent paper¹ on the physician's statement of cause of death. The most interesting part of the paper is an account of a confidential inquiry in which the certifiers who had mentioned diabetes on a death certificate during a twelve months' period in Ontario were invited to state how far in their opinion diabetes had contributed to the fatal issue. The point of the inquiry was, of course, that under most rules of selection diabetes has so high a preference that if a rigid rule is enforced, then, in a tabulation by single causes it will usually be selected. In fact in this sample the rule would have assigned four-fifths of the deaths to diabetes. In the opinion of the certifiers only two-fifths should have been so assigned. In one-third of the cases which would under rule have gone to diabetes the disease had been present and recognized for ten years or more. As Dr. Sellers remarks: "Present methods tend to make statistics of causes of death a measure of the incidence of such diseases among the population at death, under-stating certain others as a result." For many years the policy of the English General Register Office has been to try to secure for tabulation the real opinion of the certifier and to render office rules obsolete. As the late Dr. T. H. C. Stevenson used to say, it is absurd to suppose that somebody in an office knows better than the practitioner who attended the patient what was the cause of death. Yet the adoption of office rules was due not to a double dose of original sin in "bureaucrats" but to a lack of precision in certification, and there are still countries in which the level of education or standard of duty of practitioners

may compel the application of rules of selection. Indeed, in any country some certificates must always be so treated. There is good reason to believe that here the standard of certification is steadily rising.

"PERITONEOSCOPY"

Direct examination of the abdominal cavity by an endoscopic instrument is not a new procedure, and from time to time observations upon this method of diagnosis were made some years before the war. In a recent review E. B. Benedict² of Boston reports forty-eight personal examinations under the title "peritoneoscopy." Among some fifteen authors whose experiences of laparoscopy or peritoneoscopy he quotes the most extensive are those of Ruddock, who has examined over 500 cases and reports an accuracy of diagnosis in 91.7 per cent. The instrument he has devised is not unlike a cystoscope, consisting of a trocar (for putting air into the peritoneum) and a sheath into which a telescope, forceps, or diathermy connexion can be inserted. Only a local anaesthetic is required, and as a rule the abdomen is punctured just below the umbilicus in the mid-line. Air is forced in with an ordinary hand bulb, and according to Benedict the secret of successful visualization lies in having a large peritoneal air space. When free fluid is present this must presumably be tapped first. The dangers of the examination lie in the possibility of perforating the bowel, and Ruddock reports eight punctures in 500 cases, all without fatality. Other risks are those of causing haemorrhage and of spreading infection. It would seem to carry an undue risk in inflammatory conditions of the abdomen, especially when many adhesions are likely to be present and in any condition where the air distension of the abdomen might be dangerous—as, for example, severe cardiac disease. Benedict has found the investigation satisfactory, safe, and helpful in a number of conditions, of which carcinoma and cirrhosis of the liver, tuberculous peritonitis, and pelvic tumours may be mentioned. The relatively slight operation of peritoneoscopy may save the more serious laparotomy by demonstrating the presence of metastases in carcinoma of the stomach. Peritoneoscopy may be useful in the diagnosis of ascites of doubtful nature; but it must be admitted that it is in just such cases that visualization may be most difficult. Modern progress in endoscopic methods suggests that a renewed interest in direct abdominal examination may give better results in diagnosis of obscure abdominal conditions, and perhaps save some at least of those surgical explorations which reveal either an inoperable or a non-surgical state at operation. It must be confessed, however, that hitherto in this country little work appears to have been done on these lines, and only Short's³ paper of 1925 is mentioned by Benedict. Certainly with the improved technique of endoscopic instruments further observations are likely to be recorded.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

INFECTIONS OF THE HAND AND FINGERS—I

BY

NORMAN C. LAKE, D.Sc., M.D., M.S., F.R.C.S.

There is no need to emphasize that the disabilities which follow in neglected cases of infections of the hand and fingers are of the gravest economic importance. It is usually considered that the loss of an eye is one of the most serious results of any injury, but there can be little doubt that the loss of the right hand is a more severe, if less dramatic, sequel. Similarly, the patient who has lost both hands is obviously more helpless than the patient who has lost his sight completely.

In this connexion it is of some interest to note that at the Ford factory in Detroit a survey has recently been made to see what percentage of the different jobs could be carried out by disabled men. It was found that of a total of 7,882 kinds of jobs, 2,637 could be done by one-legged men and only 715 by one-armed men. It must be remembered, however, that these figures refer to the peculiarly mechanical repetition work done in mass-production factories, and they also involve an expression of great good will and helpful intention on the part of the employer. In the open labour market the one-armed man's chances are obviously much smaller than these figures indicate.

It follows, therefore, that the treatment of cases of this type deserves the most careful attention. There is possibly no part of the body in which a knowledge of anatomical features is of greater importance, for rational and efficient surgical treatment depends as much upon anatomical as upon pathological knowledge in these cases. A review of the main anatomical points must therefore form an indispensable preliminary to any considerations of treatment.

Skin and Fascia

The skin of the palmar aspect of the fingers is thick and tough, and in the vicinity of the joints it is held down to the digital extensions of the palmar fascia to form characteristic creases. The interphalangeal creases lie slightly proximal to the level of the corresponding joints, but the metacarpophalangeal crease at the base of the digits lies about half an inch distal to the knuckle-joint. Over the palm also the skin is intimately attached to the underlying palmar fascia. The creases here form the characteristic "lines" of the palmist, but have little surgical significance. A small amount of fat intervenes between skin and fascia, and is divided into a large number of small loculi by fibrous septa. Over the proximal and intermediate phalanges, too, a similar arrangement holds, while in the pulp of the distal segment the arrangement is so characteristic and important as to deserve special consideration. The object of these attachments of skin to deeper structures is clearly to prevent excessive movement of the skin during prehension, otherwise the facility with which objects are held would be considerably diminished. In the pulp of the fingers and thumb the fibrous septa are particularly well marked, and

the amount of fat is, of course, greater than in the other segments of the digit. These fibrous septa, extending from the skin to the periosteum of the terminal phalanx, divide the fat into a series of loculi disposed with their long axes vertical to the surface. The pulp is thus divided into a large number of spaces arranged rather like the cells of a honeycomb (Fig. 1).

FIG. 1.—a and b, transverse sections through proximal and distal phalanges of finger. c, longitudinal section through termination of finger. Note the loculation of the fat, especially in the terminal phalanx, and the relation of the long tendons to the epiphyseal line.

In the presence of infection, inflammatory exudations are therefore unable to spread widely, as they can do elsewhere, but are retained in the loculi, producing an extreme degree of tension which is frequently sufficient to interfere with the blood supply. This arrangement, too, provides many channels by which superficial infection of the skin can be conveyed directly down to the underlying bone. Under the skin creases there is very little subcutaneous fat, and here the tendon sheaths closely approach the surface, so that minor penetrating wounds may carry infection into them.

On the dorsal aspect of both fingers and hand the skin is much looser, to permit of flexion; this produces the characteristic creases over the backs of the fingers. These lie roughly at the same level as the corresponding joints. The dorsal subcutaneous tissue is also loose and areolar; it thus accommodates large quantities of inflammatory exudation, and is indeed the position in which such exudations tend to collect even when the causative infection is on the palmar aspect of the hand. The bed of the nail is fairly firmly attached to the underlying periosteum; the nail itself thus affords good counter-pressure to forces applied to the finger-tips, and in this way helps prehension. Only the slightest amount of to-and-fro movement can normally be detected in the nails; the range is increased and the movement becomes painful in affections underlying the nail, in its bed or in the bone.

The palmar fascia forms a dense fibrous barrier which usually prevents deep-seated pus from reaching the surface

of the palm. In the proximal half of the hand it forms a fairly continuous ensheathing layer, but in the distal half its digital prolongations separate from one another, and in the intervals the digital nerves and vessels become more superficial. At the sides the dense palmar fascia is continued as a thinner sheath covering the muscles of the thenar and hypothenar eminences (Fig. 2).

Under cover of the fascia, in an arcular interval, lie the superficial palmar vascular arch with its digital

tendons proximally. This large sheath extends upwards under the anterior annular ligament of the wrist into the forearm, terminating about two fingerbreadths proximal to the ligament. The long flexor of the thumb has a sheath of its own which extends from the base of the terminal phalanx up under the annular ligament and ends

FIG. 2.—Diagram of the palmar fascia.

branches and the digital branches from the ulnar and median nerves. At first the nerves lie deep to the vessels, but as the roots of the fingers are approached the nerves come to occupy an anterior position and run along the digits on the lateral aspects of the flexor sheaths (Fig. 3).

FIG. 3.—Lateral view of finger showing the relative positions of digital vessels and nerves.

Tendon Sheaths

Deep to the vessels and nerves lie the tendons in their sheaths. The latter afford a ready means for the spread of infection, so that special attention must be paid to their arrangement. This is subject to a little variation, but in general it may be accepted that the sheaths of the flexor tendons of the second, third, and fourth fingers extend from the base of the terminal phalanx to the distal skin crease of the palm. In the case of the little finger the theca usually extends up through the palm and becomes continuous with the large palmar bursa (common flexor sheath), which surrounds the profundus and sublimis

FIG. 4.—Transparency showing the relation of the tendon sheaths to the chief overlying structures. The horizontal lines represent the limits of the anterior annular ligament.

at the same level as the palmar bursa (Fig. 4). All the digital synovial sheaths are contained within fibro-osseous canals, formed on the deep aspect by the periosteum of the phalanges and over the joints by the glenoid ligaments thereof, on the palmar and lateral aspects by a transversely fibred arch with which the digital extension of the palmar fascia is blended. These sheaths are especially thickened where they lie over the proximal and intermediate phalanges, but opposite the joints they are thinner and more lax. Cruciate bands are usually present at the junction of these sections. Even when the sheath is distended by inflammatory exudations the tendon remains a fairly tight fit at the restricted points, and it is here that localizing adhesions may form to limit the spread of infection.

Initially during development a tendon running in a sheath has a complete mesotendon bearing the same relation to it as the mesentery does to the intestine. This special arrangement of the flexor tendons of the fingers by which the superficial one splits to permit the passage of the deep tendon does not, however, allow of the persistence of this early arrangement. Most of the mesotendon therefore disappears, but the remains can be recognized as the vincula tendinum. This small point is of special importance because the blood supply of a tendon

reaches it, at least in part, through the mesotendon. In the fingers, therefore, the vascular supply will be derived chiefly from the ends of the synovial sheath, and will receive but little reinforcement along the length of the tendon. Small vessels extend along the tendon in the synovial covering, and from them the substance of the tendon receives its nutritive supplies, mainly by transudation. It will thus be seen that the nutritive supply of the digital flexor tendons is particularly precarious. It is true that passive structures such as tendons require very little nutrition in normal circumstances, but any slight increase in tension within the theca will be sufficient to cut off the blood supply entirely, and this, of course, will lead to necrosis followed by invasion of the tendinous tissue by the organisms.

Fascial Spaces

Kanavel has described the routes by which infection spreads in the hand. By the injection of opaque materials into various regions of the palm he was able to demonstrate, both radiographically and by dissection, that the spread of these substances tended to be restricted to certain compartments, and upon this basis he was able to establish rational methods of surgical drainage. Valuable as Kanavel's work was from the anatomical point of view, we must not forget that the barriers which limited the spread of his injected materials would not, of necessity, have more than a temporary retarding effect upon the spread of organisms. As a basis for our studies, therefore, his ideas will be admirable, but in practical application we must be prepared to find that infection is only rarely limited to any one particular space or structure.

We have seen that only the thinnest layer of fibro-fatty tissue intervenes between the skin and the palmar fascia, and so loculated is this tissue that infection in the superficial layer is unable to spread beyond a short distance before the skin is perforated and spontaneous drainage stops further extension. On the dorsal aspect of the hand there are two loose areolar spaces, one between the skin and the extensor aponeurosis (the dorsal subcutaneous space) and one between the aponeurosis and the bones (the dorsal subaponeurotic space). These are the spaces in which oedema is chiefly seen in infections involving the palmar spaces, the great density of the palmar fascia preventing anything more than an undue fullness of the "cup" of the palm when deep-seated infection is present.

Deep to the palmar fascia the areolar intervals are divided into two main sections by the fascia covering the adductor transversus muscle. The palmar (mid-palmar) space is an extensive and important area lying deep to the profundus tendon and anterior to the third, fourth, and fifth metacarpal bones, with their corresponding interossei (Fig. 5). It is bounded on the inner and outer sides by partitions passing from the deep aspect of the palmar fascia to the third and fifth metacarpals respectively; the former is strong, and separates this space from the thenar space. Proximally the palmar space extends, by a narrow passage, to the deep space of the forearm, while distally it is continuous with the third and fourth web spaces and, by prolongation along the lumbrical tendons, with the dorsal subaponeurotic space. The thenar space lies between the palmar fascia and the adductor muscle, extending around the distal border of that muscle on to its dorsal aspect. It is separated from the palmar space by the fascia already mentioned; this corresponds superficially with the skin crease running along the inner aspect of the thenar eminence. Externally it extends deep to the thumb muscles as far as the first metacarpal bone,

and distally it communicates with the web spaces of the index and thumb, and, via the first lumbrical canal, with the dorsum of the hand. It has no extension to the deep spaces of the forearm.

The web spaces lie between the heads of the metacarpals and are continuations of the palmar and thenar spaces to the dorsal aspect of the bases of the fingers; there they communicate with the subcutaneous spaces of

FIG. 5.—Diagrammatic transverse section of the palm showing disposition of the various spaces, (a) The palmar space, (b) thenar space, (c) dorsal subaponeurotic space, (d) dorsal subcutaneous space, (e) common flexor sheath (ulnar bursa), (f) tendon of extensor longus pollicis, (g) extensor tendons, (h) adductor pollicis, (i) palmar fascia, (k) digital vessels and nerves.

the dorsum of the hand. The deep fascial space of the forearm lies under the profundus tendons and superficial to the pronator quadratus. It continues proximally, superficial to the interosseous membrane, so far as the origin of the deep muscles from that structure.

It must be realized that the common flexor sheath lies immediately superficial to the palmar space, while the sheath of the flexor longus pollicis is surrounded by the thenar space; infections therefore extend with ease from one structure to the other.

Joints

The interphalangeal and metacarpo-phalangeal joints are all in fairly intimate relation to the tendon sheaths, and it has already been mentioned that their volar (glenoid) ligaments form part of the thecal canal. The phalanges themselves have, before the age of about 20, an epiphysis at their proximal end, and the same applies to the first metacarpal. The other metacarpals have an epiphysis at the head. The blood supply to that part of the bone derived from the epiphysis reaches it largely along the capsule of the joint, through the section of the digit immediately proximal (see Fig. 1). This is important in the case of the terminal phalanx, for when the pressure of exudation in the terminal segment cuts off the blood supply to the bone its base is still able to derive a supply in this way, and so bony necrosis rarely extends beyond the level of the epiphyseal line (even when this is completely ossified in the adult), and infection of the interphalangeal joint is thus prevented; the insertions of both flexor and extensor tendons remain intact and the theca is not involved.

The main palmar bursa (common flexor sheath) is considerably restricted as it passes deep to the anterior annular ligaments; at this point, therefore, the spread of infection may be at least temporarily arrested. For the same reason any subsequent adhesions are always densest

at this level. Since the theca of the little finger is continuous with the main bursa it is obvious that the nervous and vascular supplies of the ulnar border of that finger must cross the sheath. The vascular and nervous supplies of the radial side of the index finger cross the proximal end of the theca of that finger deep to the palmar crease in this situation. The thumb sheath is deeply buried as it passes between the muscles of the thenar eminence. It is important to note that this sheath is crossed superficially by the branches from the median nerve which supply these muscles.

H. G. MILLER, M.B., B.S.

House-physician to the Royal Victoria Infirmary,
Newcastle-upon-Tyne

Investigations into the physical standards of sample groups of school children of various social classes have shown in most instances that the children of the upper classes are taller and heavier and have blood richer in haemoglobin than children of the poorer type; while Spence has shown that in Newcastle there was a wide difference between the health and development of the infants in his sample group of "city children" and the similar group of "professional class children" which he examined.

The present investigation was carried out in an endeavour to assess the result of an improvement in environment at an early age on one of two groups of children of strictly comparable heredity. The most hopeful approach seemed to be in comparing, by the same individual technique as that used by Spence, a group of slum children with children living in the physically favourable environment of an orphan institution, the latter having a heredity comparable to, and certainly no more favourable than, the former. The group chosen were the seventy-five children between the ages of 5 and 14 years residing in the Newcastle Education Committee's Ponteland Children's Home—the "Ponteland children"—and a similar number of children of identical age and sex distribution attending the Jubilee Street Council School, situated in a poor part of Newcastle—the "Jubilee children."

The difference in environment may be inferred from the fact that the Ponteland children were living in a pleasantly situated self-contained village some miles from Newcastle, eating a diet costing an average of just over four shillings and sixpence a head per week (and purchased *en bloc*), which was properly balanced and included meat at least once a day and an average of just under one pint of fresh milk daily. The parents of 50 per cent. of the Jubilee children were unemployed, and these children were presumably eating a diet costing at any rate not more than three shillings per week which the Unemployed Assistance Board provides for all the necessities of life; with, in addition in certain cases, free milk daily and in a very few cases (not 5 per cent.) free meals. On inquiry not more than 10 per cent. of the Jubilee children had eaten protein of any kind at their midday meal on the day of examination—broken biscuits appeared to be a staple article of diet.

The two groups of seventy-five children were carefully examined by me with reference to their general condition, their height, weight, and chest measurement, their teeth, and their haemoglobin indices.

The Ponteland children were not admitted to the home until the age of 3, and no accurate information was obtainable about their environment during the first three years of life. All that can be said of these early years, which are shown to exert a crucial influence on the later development of the children, is that they were spent in the large majority of cases either in a Poor Law institution or under very unfavourable conditions of life outside. It seems improbable, however, that under normal conditions any more sharply defined groups as regards environment will be obtainable.

The assessment of general condition was of course subjective, but I endeavoured to take into account colour, muscle tone and stance, skin temperature, and general alertness.

General Condition

| | Ponteland | Jubilee |
|--|-----------|---------|
| Optimum (children in every way fit) .. | 37 | 7 |
| Poor (children obviously unfit) | 1 | 9 |
| Others | 37 | 59 |

For comparisons of weights and heights optimum zones were made by weighing and measuring several hundred children in Newcastle high schools and preparatory schools, plotting their weights and heights on graphs, and constructing zones to include the large majority. Separate zones were made for boys and girls, but for convenience of reference the results are here grouped together:

| | Heights | | Weights | |
|-----------------------------|-----------|---------|-----------|---------|
| | Ponteland | Jubilee | Ponteland | Jubilee |
| Children above optimum zone | 0 | 0 | 0 | 1 |
| Within | 24 | 19 | 10 | 15 |
| Below optimum zone | 51 | 56 | 65 | 59 |

As will be seen, the children of both groups fall almost completely below the optimum zones of the "high-school" children. When the zones used were based on the figures of the British Association's Anthropometric Committee (1875-83), employing the committee's average as an upper limit and a line 10 per cent. below this as the lower limit of the zone, the Ponteland and Jubilee children are seen to fall very well within these limits and show no significant discrepancy—that is to say, the difference between the weights and heights of the high school and the Ponteland children is of the same order as that between the high school and the Jubilee children.

| | Heights | | Weights | |
|----------------------------|-----------|---------|-----------|---------|
| | Ponteland | Jubilee | Ponteland | Jubilee |
| Above B.A. average zone .. | 12 | 17 | 20 | 13 |
| Within | 61 | 57 | 40 | 46 |
| Below | 2 | 1 | 15 | 11 |

It is of interest to note that when the weights and heights of the high school group were plotted against these B.A. zones the following results were obtained.

| | Heights | | Weights | |
|--------------------------|--------------|----|--------------|----|
| | 93 per cent. | | 84 per cent. | |
| Above average zone | 7 | .. | 16 | .. |
| Within | 0 | .. | 0 | .. |
| Below | .. | .. | .. | .. |

¹ Spence, J. C. (1934): *Investigation into the Health and Nutrition of Certain of the Children of Newcastle, Newcastle.*

Quite evidently the British Association Anthropometric Committee's averages, assessed as they were from the measurement of children preponderantly of the poorer classes, should be taken not as normal weights and heights but rather as depressed averages.

The chest circumference measurements, taken in full inspiration, were recorded on the case-sheets, but in my opinion they depend so much on the enthusiasm of the examinee as to be valueless.

Examination of the teeth revealed what I believe to be significant differences.

| | Ponteland | Jubilee |
|---|-----------|---------|
| Perfect dentition: No caries or history of caries | 8 | 2 |
| Hypoplasia, with no gross caries or history of caries | 15 | 3 |
| Gross caries or history of caries | 52 | 70 |

These figures show that twenty-three of the Ponteland children were free from caries, as against only five of the Jubilee children. In addition, active extensive caries (four teeth or more involved) was present in six of the seventy-five Ponteland children, as opposed to twenty of the seventy-five Jubilee children. The most significant differences, however, appeared in the haemoglobin indices (estimated by the Sahli haemoglobinometer—standard = 14 grammes per 100 c.cm.).

| Hb percentage | Ponteland | Jubilee |
|--|-----------|---------|
| Above 85 per cent. | 13 | 1 |
| 70 to 85 per cent. | 55 | 47 |
| Below 70 per cent. | 4 | 27 |
| Below 65 per cent. (also showing clinical anaemia) | 0 | 6 |

Conclusions as to the significance of the differences recorded in dealing with such small groups of subjects must of necessity be tentative. Briefly, while the weights and heights of the two groups showed no appreciable difference, both being distinctly suboptimum, the general condition, the teeth, and the haemoglobin indices of the slum children were distinctly inferior to those of the children's home group.

These facts suggest that although improvement in environment after the age of 3 had led to distinct improvement in general condition, teeth, and blood, it was without effect on subsequent growth. It would appear that such growth was decisively affected by conditions during the first three years of life, and that subsequent improvement in environment did little to modify this. But the improved conditions of the Ponteland children in other respects did seem to be accompanied by a heightened resistance to disease, and as a community the children's home appears to have a suggestively low incidence of illness. On these and other grounds weight and height *per se* seem to be falling into increasing discredit as indices of health.

Summary

A comparison of a group of school children from a poor part of Newcastle with a similar group from a children's home revealed that although the weights and heights of the two groups showed no appreciable difference and were both suboptimum, the general condition, the teeth, and the haemoglobin indices of the children's home group were distinctly superior to those of the slum children.

I wish to thank the various education authorities and individuals who so kindly facilitated the collection of the data used; and Dr. J. C. Spence for his constant stimulation and advice.

THE MEDICAL PROFESSION AND NATIONAL DEFENCE

DUTIES OF DOCTORS AND NURSES

The following announcement was made by the Ministry of Health on Tuesday night:

The Ministry of Health is receiving inquiries from doctors and nurses asking what they would be expected to do in the event of hostilities. Some already have commitments to the Forces or to the A.R.P. or other public services. Those who are not committed in this way but are attached to hospitals would no doubt be required there, and should in any case keep in touch with their hospitals.

Doctors and nurses in private practice may be able to afford valuable assistance in local air raid precautions schemes, and if they are willing to help in this way they should get into touch with the medical officer of health. They may also be required for treating casualties in their own homes.

The British Medical Association, at the request of the Government, has compiled a register of doctors who are prepared to serve in various capacities, and use will be made of this register for importing doctors into a district where there is urgent need of additional medical assistance. Any doctor who has not yet responded to the inquiries from the British Medical Association should do so without delay, and if he does so he will, when need arises, be told where and in what capacity his services are required.

Until similar machinery is instituted for the nursing profession, any nurses who are willing to offer their services but are not in touch with hospitals should enrol with the local branch or head office of the College of Nursing, whether they are members or not. This applies only to State-registered or certificated nurses, including those who have given up practice.

There is no need for doctors or nurses to offer their services directly to the Ministry.

HOSPITAL ACCOMMODATION FOR AIR RAID CASUALTIES

The following statement on hospital accommodation for air raid casualties was issued by the Ministry of Health on September 22.

The Ministry of Health has made rapid progress in organizing the hospital system to meet any emergency that may arise, and it is now possible to give a general picture of the proposals.

Hospital authorities were told by the Ministry in August that they would be expected, if an emergency actually occurred, to empty as many beds as possible by sending home those patients who are fit to go. It is estimated that most hospitals would be able to clear between 30 per cent. and 50 per cent. of their beds in this way. No hospital is expected to take any step of this kind until asked to do so by the Ministry, and it is unnecessary to say that no such request has yet been made. The majority of patients going home would be sitting or walking cases, and hospitals have been asked to arrange for transport of their cases themselves by means of voluntary effort. The Women's Voluntary Organization would help in this work. Once at home discharged patients would, of course, come under any general arrangements for evacuation for their districts.

Simultaneously with sending patients home, certain hospitals, for the most part the larger general ones in the more congested areas, would "decant" patients fit to be moved, though not yet fit to go home, to other institutions which are fully capable of continuing the

necessary treatment, but which would be less useful for receiving air raid casualties. In the London area thirty-four hospitals have already been designated for "decanting," and detailed plans prepared for removing between 3,000 and 4,000 patients by ambulance trains to towns 50 miles or more from London. The patients would be conveyed to the railway stations by motor coaches converted to carry stretchers. The necessary stretchers are available and held centrally for distribution if and when required. Fittings for the coaches have been made, and 300 can be converted into ambulances at twelve to twenty-four hours' notice. The owners of the coaches know exactly where they would report, and what journeys they would be required to make. The necessary arrangements have also been made with the railway companies. Other hospitals in the London area would "decant" patients a shorter distance in order to empty beds, and these would make the whole journey by bus.

The Ministry has been in close touch with the London County Council throughout. As already announced, one of the senior medical officers of the County Council is acting as hospital officer for the London district. The Ministry has also conferred with representatives of all the voluntary hospitals involved in the "decanting" scheme, and explained the proposals to them in detail; and before the end of the week conferences will have been held with representatives of all the other voluntary hospitals in the district. Conferences have also been held with all the medical officers of health of the counties and county boroughs in the Home Counties, and of the towns receiving the patients decanted from London. Arrangements are being made in these towns for meeting the ambulance trains and conveying the patients to designated hospitals. It may be added that the London County Council has been authorized to provide surgical equipment at some of the larger hospitals not at present used for surgical cases, so that these, which have a good deal of available ward room, would be fully equipped for dealing with casualties if necessary.

Plans for clearing hospital beds by "decanting" patients have similarly been worked out in the provinces by the Ministry's hospital officers. These officers are in touch with the local hospital authorities, and in addition conferences have been held in Whitehall with the medical officers of health of the large cities.

So far the plans made have been concerned principally with the utilization of existing accommodation and equipment. The Ministry has, however, taken steps for the acquisition of additional equipment which will be distributed when available to different centres. Meanwhile, information has been collected as to the stocks of bedsteads, bedding, and other necessary equipment held by the trade in various towns, and, if necessary, arrangements would be made to supplement existing stocks from these sources.

While the Ministry has now conferred directly with a great many hospital authorities, both municipal and voluntary, it has not yet been possible to do so with all of them. It is intended very shortly to arrange a further series of local conferences at which Dr. Hebb, the Principal Medical Officer advising the Minister on the emergency hospitals organization, will discuss details of the schemes with the authorities.

In a later communication the Ministry urges private owners of cars which are not already earmarked for transporting patients and which are not being used for any other essential purpose to assist in this evacuation by getting into touch with their local hospital and offering to send their cars (with drivers) to the hospital for use if required as conveyances for the patients.

L.C.C. Emergency Measures

The London County Council has taken prompt and energetic steps to make available the greatest possible

number of beds in the event of outbreak of war, and we understand that the arrangements that have been made in conjunction with the Ministry of Health will put at the disposal of the public between 20,000 and 25,000 beds for emergency treatment in the County of London. In addition to that arrangements have been made by the Ministry to transfer between 3,000 and 4,000 patients from voluntary and municipal hospitals to hospitals in towns situated some fifty to sixty miles outside London. In addition to plans for the evacuation of cases all available extra beds and mattresses have been put up throughout the whole of the L.C.C. hospital service.

The medical superintendents of L.C.C. hospitals have been advised to evacuate patients who would be fit to be discharged a day or two earlier than would otherwise have been the case, and to select other patients who could be discharged without hardship to themselves immediately on the outbreak of war. They have been advised, too, in co-operation with the general practitioners in the areas of the hospitals, to defer the admission of patients who are not in urgent need of treatment—for example, patients with hernia, varicose veins, etc. Similarly, in the tuberculosis hospitals the admission of non-urgent cases has been postponed. Fever hospitals have been instructed not to admit cases of such mild infectious diseases as chicken-pox and mumps. These hospitals have been "up-graded" by the supply of additional surgical equipment and dressings so that they will be able to take their place as acute casualty hospitals. Where it has been possible each fever hospital has been divided into two parts: (1) for the admission of fever cases, and (2) for the treatment of air raid casualties.

The L.C.C. hospitals are also being provided with an extra stock of fuel, the equivalent to one month's extra stock of drugs, dressings, etc., and an extra stock of food-stuff equivalent to approximately one month's supply. The hospitals are also actively engaged in making arrangements for the blacking out of their buildings in accordance with the police regulations and for introducing such other emergency measures as are dictated by circumstances.

Local News

FRANCE

[FROM OUR CORRESPONDENT IN PARIS]

Professor Clovis Vincent

Dr. Vincent's work as a surgeon in Paris has proved of such value that the Assistance Publique, which is responsible for the administration of this city's public hospitals, created some time ago a special hospital service under his direction. He has now been appointed a professor at the Faculty of Medicine, with clinical neurosurgery as his specialty. The creation of this new chair has been made possible by a donation from the Rockefeller Foundation in recognition of Vincent's pioneer work.

Fiftieth Anniversary of the Pasteur Institute

On October 26 the fiftieth anniversary of the Pasteur Institute will be celebrated in the Grand Amphithéâtre of this institution in the presence of M. Lebrun, President of the Republic, the Minister of Public Health, and many others. This celebration will coincide with the first International Congress of French-speaking Microbiologists, all the delegates to which have been invited by the Director of the Pasteur Institute to be present at the celebration. Inquiries with regard to the congress should be addressed to the secretary of the Association des Microbiologistes de Langue Française, Institut Pasteur, 28, Rue du Dr. Roux, Paris, XV.

AUSTRALIA

Poliomyelitis in Victoria

The Director of the Walter and Eliza Hall Institute of Research in Pathology and Medicine, Dr. Charles H. Kellaway, has just presented his annual report for the year 1937-8. In Victoria, during the epidemic of poliomyelitis which only came to an end in February of this year, no difficulty was experienced in transferring the poliomyelitis virus to monkeys; four strains are now available for future work. Monkeys recovering from the inoculation of the local virus, however, showed only partial immunity to the regularly fatal "M.V." strain. During the epidemic there were collected for subsequent investigation many samples of serum from cases early in the febrile period and from contacts, at the time of contact and four to eight weeks later.

During the early winter of 1937 some two hundred individuals were given intranasally two inoculations of living, egg-adapted, "Melbourne" influenza virus, a strain which can be clearly differentiated antigenically from the "W.S." and "swine" strains. No epidemic of influenza occurred, so the experiment has only shown the harmlessness of the procedure and an increased antibody response after inoculation in a few of the subjects. Work on "Q" fever has continued, and other researches have been concerned with the problem of cell injury, the liberation of histamine, and with various clinical problems.

Correspondence

Convalescent Serum in Infantile Paralysis

SIR,—The case against the therapeutic value of convalescent serum was summarized in your columns by me some five years ago (December 30, 1933). The information upon which it was based is generally accessible, and to restate the case now would be a waste of your space. Professor G. R. Girdlestone (*Journal*, September 24, p. 678) is right in saying that in the past the use of serum has not always been such as to provide reliable evidence of its value, and his own use of it—upon which he formed his favourable view—was admittedly of this order. There is an increasing weight of evidence based upon adequately controlled observation that serum treatment has no value, but there is also experimental evidence even more conclusive to which Professor Girdlestone does not refer—namely, the fact, long known, that this serum does not modify the course of the disease in the inoculated monkey when given under the only conditions possible in the human subject—that is, after the onset of symptoms. Recent pathological work has shown why this must necessarily be so. Therefore the serum treatment of poliomyelitis is as lacking in rational basis as in practical justification. Nor can we reasonably hope that the future will reverse this verdict of experience in the past. Dosage has been steadily increasing since Netter in 1910 introduced this treatment, yet no one has been able to claim better results than he claimed for the use of what later workers regard as quite absurdly inadequate dosage.

It is therefore essential that Professor Girdlestone's act of faith should be recognized as such rather than as a scientific judgment based upon facts, and even more important that the hopes of the public should not be cruelly raised. The cherishing of therapeutic illusions by the distressed parents of a sufferer from acute poliomyelitis must place the family doctor, the consultant, and the local health authority in a wholly false position in which it is

not equitable that they should be placed. Two recent letters in the *Times* show how easily this may happen, and the situation is one that Professor Girdlestone cannot possibly wish to bring about.

In his first letter, with a candour I respect, he expressed himself as aware that he was venturing out of his proper sphere. Yet it is in these circumstances that acts of faith become the easy substitutes for reasoned judgment, and dangerous ones in that they bear the appearance of a medical authority they do not in fact possess.—I am, etc.,

London, W.1, Sept. 24.

F. M. R. WALSHIE.

Prognosis of Anxiety States

SIR,—In his interesting paper on prognosis of anxiety states in the *Journal* of September 24 (p. 649) Dr. Arthur Harris, speaking of follow-ups, says: "Luff and Garrod have traced their cases for three years and Ross some of his cases for five years and the rest for three years." So far as my cases are concerned this is a complete mis-statement of fact. If Dr. Harris will glance at the table on page 79 of my book, *An Enquiry into Prognosis in the Neuroses*, he will see that I had traced the after-histories of 943 patients over periods varying from three to thirteen years. If he will look at the top line, which refers to patients discharged from the Cassel Hospital in 1921, he will see that the after-histories of twenty-two out of fifty-eight patients were known at the end of thirteen years. On the next line, referring to the 1922 discharges, it will be found that another forty-three patients out of ninety-eight discharged in that year were known about at the end of twelve years, and so on. At the end of ten years 102 patients out of 254 were known about.

I must suppose that he was misled by a note printed after the 1929 discharges, which said that there were no more five-year histories after that date, a thing that is of course obvious, seeing that the inquiry ended in 1934; but the note said nothing about the years before 1929.

Dr. Harris's paper is one of great value, all the more as he recognizes the immense difficulties surrounding an inquiry of this sort. I would, however, ask him to look also through pages 37-55, with a hope that he may become less pessimistic about patients whose symptoms are of long standing.—I am, etc.,

London, W.1, Sept. 24.

T. A. ROSS.

The Nature of Viruses

SIR,—The annotation entitled "The Nature of Viruses" (*Journal*, September 24, p. 667) accepts as the "hall-mark of living things in the final issue" their possession of an "independent metabolism." Presumably these words may be held to signify that this possession differentiates "living things" from something else. The word "independent" has, however, no meaning unless that of which the affair in question is independent is stated. Is this an invitation by the writer to conceive the metabolism of "living things" to be characterized by independence of their environment? If not, in what then does the alleged independence consist?

It has proved necessary to abandon one by one the traditional distinctions drawn between "living things" and other terrestrial units; it does not seem likely that the distinction cited in the article will enjoy any better fate. It would occupy too much space to set out the evidence against its validity. I prefer to use what you will allow me for suggesting that the time has come when the conception of a fundamental difference in nature between

"living" and "non-living" should be abandoned in favour of the more comprehensive one of differences in the behaviour of different groups, arising solely out of differences in their organization.

There are broad differences between the behaviours of the atom unit, the molecule unit, and the colloid unit, all these being groups in the sense in which I am using this word. Any group belonging to any of these three classes which is stable for an appreciable period of time may conveniently be conceived and described as an *individual* for the period of its stability. The "things" which have hitherto been called "living" are otherwise describable as colloid individuals, different from the atomic and molecular individuals not as to the nature of their elements but as to their organization only. The time-occupying stability of all groups (individuals) may be interpreted as a balance phenomenon, the terms of the balance being group \rightleftharpoons environment. To no group, and to no detail of the organization of any, may the term "independent," in the literal sense of this word, be properly applied. The term "parasitic" conventionally describes a peculiar relation whose essential feature is, that the immediate environment of some individual of the colloid-group class is constituted by another individual of the same class.

If the word "living" is continued in use it should be used to connote a peculiar organization and the peculiarities of behaviour that go with this. There is no longer warrant for conceiving that the elements which constitute the individual of the colloid-group type differ in nature from those which constitute the atomic and molecular individuals of the earth's surfaces.—I am, etc.,
K. W. MONSARRAT.
London, W.1, Sept. 25.

Diagnosis of Whooping-cough

SIR,—One regrets that in a five-page critical review of laboratory aids to the diagnosis of whooping-cough (*Journal*, September 17, p. 613) Dr. A. B. Donald was able to devote only four lines to agglutination tests, briefly arriving at a conclusion that such tests were unreliable and useless as a method of diagnosis.

One hesitates to accept this dogmatic statement without details of the method adopted, because it is well recognized that the *Haemophilus pertussis* has four phases of growth *in vitro*. Whereas Phases II and IV give little or no agglutination and are in fact "rough" colonies, Phases I and III are "smooth" and virulent, and are actively agglutinated by convalescent and possibly third- and fourth-week sera.—I am, etc.,
A. GORDON MOORE.
Watford, Herts, Sept. 20.

The Occipito-posterior Case

SIR,—It was with horror and dismay that I read Dr. David Price's letter (*Journal*, September 17, p. 638). Coming as it did a week after Professor Chassar Moir's excellent paper on this subject, the horror was intensified. There are a few points in the letter which cannot go unchallenged. To apply forceps before the os is fully dilated is, at the best of times, undesirable; still less so if it is made a routine. His statement that he has never regretted the use of forceps, whether the os is fully dilated or not, leaves no hope of salvation for him. Does he really diagnose the occipito-posterior position by failure to extract with forceps? I should have thought that after thirty-five years he would be aware of the value of vaginal examination with the hand and fingers. How does he diagnose a breech presentation? By applying forceps and seeing what he pulls out, in the manner of a lucky dip? Mechanical rotation seems to be the least serious of his

errors, although I had hoped that this was being abandoned. For his courage in confessing his errors in the *Journal* I have nothing but admiration. I, personally, would never have been brave enough to do it.

Finally, may I plead with Dr. Price to give Nature a chance in his next case. I venture to assert that he will be amazed at Nature's efficiency.—I am, etc.,
STANLEY WAY.
Newcastle-upon-Tyne, Sept. 19.

Medical Evidence at Inquests

SIR,—There have been two unfortunate occurrences in my experience in cases where the coroner has engaged a professional pathologist (now dead) to perform the necropsy. In the first I was invited, as an act of courtesy, to see the examination; on arriving I found it completed and a diagnosis made of death from pulmonary embolism. At my request the cervical vertebrae were examined, and there was found the fracture which had been suspected during life. The actual cause of death was the pressure on the medulla of a haematoma resulting from this injury. The other case was one of Landry's paralysis where the spinal cord was not even looked at. As the patient had been a healthy young man it does not need much imagination to understand the pathologist's difficulties.

Surely when the coroner thinks it important to employ an outside medical man—and in many cases there may be a good deal to be said for his doing so—it is very desirable that the deceased's own doctor should be invited to attend at the necropsy and should be paid for doing so.—I am, etc.,
W. M. PENNY.

** This correspondence is now closed.—ED., *B.M.J.*

Tuberculosis Dispensaries or Chest Clinics?

SIR,—Dr. G. Gregory Kayne (*Journal*, September 17, p. 634) introduces his solution of this question with the words "failing education of the public to recognize that disease is not a stigma. . . ." I should like to ask whether we could not help to eradicate the peculiar stigma attaching to pulmonary tuberculosis. I suggest two moves in this direction.

First, we should be less squeamish in talking about tuberculosis to patients. The present attitude is instilled into the student and stays with most doctors, who will refer to "lung weakness," "pleurisy," "Koch's bacillus infection," or even "K.B."—in fact, the disease is hedged about with almost as many polite evasions as a water-closet. Even the universal "T.B." is a stupid description for the use of laymen, especially in the common but oddly senseless form of "Smith is T.B." The evasive term is, of course, a symptom of taboo, but its continued use encourages the persistence and growth of this taboo. Moreover, the use of these evasions on certificates and elsewhere often means that the treatment of this disease is advertised by its failures and not by its successes.

Secondly, I suggest that by the use of the word "consumption" we swing from polite evasion to the opposite, and no more desirable, extreme of melodramatic exaggeration. Yet even modern textbooks use such sentences as "Most consumptives find . . ." in such a way that the patient with a small, arrested, and inactive lesion is included under a term which seems to describe a sort of walking incinerator. In spite of a certain pardonable academic snobbery in favour of the old-fashioned, is it not now time for humane as well as for scientific reasons to abandon this frock-coated phraseology?—I am, etc.,
E. P. EDMONDS.
Maidstone, Sept. 21.

Obituary

SIR ANDREW MACPHAIL, M.D., C.M., LL.D.
Late Professor of History of Medicine, McGill University,
Montreal

We much regret to announce the death in Montreal on September 23 of Sir Andrew Macphail, the distinguished Canadian who held the chair of history of medicine at McGill University for thirty-one years, and was known on both sides of the Atlantic as a writer of singular force and lucidity.

John Andrew Macphail came of Highland Scottish stock. He was born on

November 24, 1864, at Inverairnie, Prince Edward Island, where his father, William Macphail, farmed in the Orwell district among Gaelic-speaking settlers. From Prince of Wales College in Charlottetown he entered McGill University and graduated B.A., continuing his studies in the medical school and supplementing them with a course at the London Hospital, where (in his own words) he observed operative surgery under the hand of Frederick Treves, "that first of modern English surgeons, at the time when he was perfecting the operation for perityphilitis, the term by which in those days appendicitis was described." He took the M.R.C.S.Eng. in 1889 and graduated M.D., C.M. at McGill in 1891; four years later he was appointed professor of pathology at the University of Bishop's College at Lennoxville, returning soon afterwards to

Montreal as pathologist to the Western Hospital and the Protestant Hospital for the Insane. For ten years he held these posts and engaged in private practice, having meanwhile married the daughter of a wealthy citizen of Montreal.

From boyhood Andrew Macphail had had a strong literary bent, and as an impecunious medical student at McGill University he reported occasionally for the *Montreal Star*. Independent means and greater leisure allowed him to indulge further his gift for writing. In 1905-6 he published *Essays in Puritanism* and the *Vine of Sibmah*, and after his appointment as professor of history of medicine in 1906 he published further essays on political and philosophical subjects: he was also Editor of the *Canadian Medical Association Journal* for some time, and edited from Montreal a quarterly review,

The University Magazine, to which the best Canadian writers contributed.

In August, 1914, Andrew Macphail at once volunteered for duty abroad; he served first in France with the Sixth Canadian Field Ambulance, and in the latter part of the war he was with the medical headquarters staff in London. For his services he received the honour of knighthood in 1918 and the O.B.E. soon afterwards. During the war he had compiled an anthology, *The Book of Sorrow*, and a memoir of his friend and colleague John McCrae, the brilliant Canadian physician, under the title of McCrae's famous poem *In Flanders Fields*. He returned to Canada to take up the duties of his chair, spending every summer on the farm in Prince Edward Island, where he delighted to entertain old friends. During the next few years he was

engaged on the *Official History of the Canadian Forces in the Great War, 1914-19: The Medical Services*. In this admirably written book he had no hesitation about entering the arena of political controversy in order to emphasize the moral to be learnt from the difficulties with which the Canadian Medical Services had to contend in the earlier years of the war. It stood out among other works of the time by reason of its literary excellence, the vigorous style of the author, and the clear-cut lessons he taught. In 1926 he gave an address on American methods in medical education at the congress of the American College of Surgeons in Montreal, and the full text of this piece of writing, remarkable alike for its style and its outspokenness, appeared in the Educational Number of the *British Medical Journal* in the following year. Not long afterwards he wrote for the *Quarterly Review* a

drastic analysis of the published diaries of Sir Henry Wilson, and this, with his essays on Colonel House and T. E. Lawrence, was republished in a book, *Three Persons*. In 1931 his last book, *The Bible in Scotland*, appeared, and the Royal Society of Canada awarded him the Lorne Pierce medal for outstanding merit in Canadian literature. For some years before then his eyesight had deteriorated and writing became more of an effort, but in 1933 he contributed to these columns an address on "The Source of Modern Medicine."

Sir Andrew Macphail among his friends was a man of great charm and a most instructive and pithy talker. Our portrait is from a copy of the painting by Alphonse Jongers in 1924, which Macphail gave to the late Editor of the *British Medical Journal*, Sir Dawson Williams, with whom he was on terms of warm friendship.

The sudden death of Dr. FREDERICK THOMAS ALEXANDER LOVEGROVE on June 24 in Perth saddened the whole of the medical profession in Western Australia. Dr. Lovegrove was universally admired and respected. He was the friend of every medical practitioner in the State, for he came into contact with all of them at frequent intervals in his capacity as Government Medical Officer. Up to within a few hours of his death he was engaged in his ordinary duties, and his sudden end was a shock to his family as well as to his colleagues. Dr. Lovegrove was born in 1875. He was educated at Merchant Taylor's School, Crosby, near Liverpool, and at University College, Liverpool, then part of Victoria University. Qualifying in 1898 with the diplomas M.R.C.S., L.R.C.P., he later took the M.B., Ch.B. He held resident posts at the Children's Hospital, Liverpool, and at the Royal Infirmary, and was Holt Scholar in Anatomy at the University. For a period he served as a ship's surgeon, and then came out in 1900 to Western Australia, where he had two uncles practising medicine, one of them being Principal Medical Officer and Commissioner of Public Health. Dr. Lovegrove entered into practice at Perth and Yarloop, but in 1902 he returned to England, where, after travelling on the Continent for some time, he went to sea again as ship's surgeon. Western Australia, however, called him back, and in 1906 he practised successively at Yarloop, Bremer Island, and Tambellup until the outbreak of the war. After four years' service, during which he attained the rank of lieutenant-colonel, he became, on his return to the State, O.C., No. 8 Australian General Hospital at Fremantle. Resuming private practice, he resided at Tambellup and Dumbleyung, until in 1928 he was appointed Government Medical Officer in connexion with the State Insurance Department. He is survived by a widow and four sons.

Mrs. HESTER DILL SMITH, who died on August 3 at Clogher, Co. Tyrone, was the daughter of the late Rev. W. A. Russell of Strabane and wife of Lieutenant-Colonel Henry Smith, C.I.E., M.D. Many old friends and fellow-students of hers in the British Isles, in India, and in the United States will remember affectionately a personality in which the stern Ulster Presbyterianism of her early environment was happily blended with innate gentleness, generosity, and courage. Hester Dill Russell decided early to become a medical missionary, and at the age of 20 began her student career at the London School of Medicine for Women and the Royal Free Hospital. She qualified M.B., B.Ch., B.A.O. in 1891, and joined the Church of Scotland Medical Mission at Poona under Dr. Letitia Barnard. Later she was transferred to Gujrat in the Punjab. There she met Captain Henry Smith of the I.M.S., who was also a native of Tyrone, and after completing her five years' service with the mission she resigned and they were married. After Captain Smith's transfer to Jullundur, and later to Amritsar, family duties did not allow Mrs. Smith to pursue a whole-time medical career. Her previous medical experience was, however, of great assistance to her husband in many ways, especially in following up the immense number of cases of cataract operated on by "Jullundur Smith." Their union was a particularly happy one, founded on mutual esteem, unity of spirit, and abiding affection.

Dr. JOHN WALKER of Paisley died recently at the age of 61. Dr. Walker was a student of St. Mungo's College, Glasgow, and qualified L.R.C.P., L.R.C.S.Ed., L.R.F.P.S. Glas. in 1903. He was in general practice in Paisley for over thirty-two years and was a member of the British Medical Association for almost as long. "A. J. D. W." writes: By the death of John Walker, Paisley has lost one of its best-known citizens. Dr. Walker built up a large practice by his devotion to his work and won the esteem and affection of his patients. He will be especially missed by the poorer section of the community, to which he was both physician and friend. For many years he had

been, on the outdoor staff of physicians of the Royal Alexandra Infirmary, Paisley. Among various organizations in which he was particularly interested were the Salvation Army and the Paisley Highlanders' Association. He took an active part in public life, having been returned for Paisley Town Council as the member for the Second Ward by an overwhelming majority in 1933—an indication of the esteem in which he was held—and he again won the seat in 1936. In December, 1937, he retired from the council owing to ill-health. Dr. Walker is survived by his wife and two sons.

The following well-known foreign medical men have recently died: Professor MAX KAPIS, director of the surgical clinic of Wurzburg University, aged 57; Professor JOHANNES LANGE, director of the nerve clinic at Breslau University and president of the Association of South Eastern German psychiatrists and neurologists; and Dr. ALPHONSE LABBÉ, honorary professor at the Nantes School of Medicine.

Universities and Colleges

UNIVERSITY OF LONDON

UNIVERSITY COLLEGE

The following lectures will be given at University College, Gower Street, W.C.1, during the first term: Four lectures by Dr. Phyllis Tookey Kerridge on "The Physiology of Hearing and Speech" on Mondays, October 10, 17, 24, and 31, at 5 p.m.; five lectures by Dr. R. J. Lythgoe on "The Physiology of Vision" on October 13, 18, 20, 25, and 27, at 5 p.m.; three lectures by Dr. J. F. Danielli on "The Permeability of Membranes" on Mondays, November 7, 14, and 21, at 5 p.m. All the above lectures are open to the public without fee or ticket.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The following awards of scholarships for 1937-8 are announced: *St. Dunstan's Exhibition*: Kathleen N. Berger. *Isobel Thorne Scholarship*: Josephine M. Lord. *Special A. M. Bird Entrance Scholarship*: Vera J. Cutler. *Mabel Sharman Crawford Scholarship*: Jessica Mestel. *Sir Owen Roberts Memorial Scholarship*: Barbara J. H. Broadwood and Margaret V. Teichmann. *A. M. Bird Clinical Scholarship*: Mrs. B. J. Clymo. *Alfred Langton Scholarship*: Alison D. Wells. *Ellen Walker Bursary*: Anne Stephen. *Flora Murray Bursary*: Elsie E. Whatley. *Emma Beilby Bursaries*: Jean M. Holtzmann and Mary L. Mittell. *Special Bursaries*: Marjorie K. Cole and Inez Hewitt. *A. M. Bird Postgraduate Scholarship in Pathology*: Nora F. T. Crowley, L.R.C.P., M.R.C.S. *Mabel Webb and A. M. Bird Research Scholarship*: Marjorie V. N. Suds, M.B., B.S., D.T.M. and H.

ROYAL DENTAL HOSPITAL OF LONDON (SCHOOL OF DENTAL SURGERY)

The prize distribution and conversazione of the Royal Dental Hospital of London (School of Dental Surgery) will be held at the Royal Dental Hospital on Tuesday, October 4, at 8 p.m. Mr. Herbert L. Eason will preside.

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—Eugenie C. Illingworth, N. Wood.
M.B., Ch.B.—(Part I): N. K. Barber, F. Debney, R. G. Dennis, P. A. Dobb, J. H. Foxton, A. Greenwood, A. Markey, A. Percival, J. G. W. Pickering, Helen M. Secker, W. Sheffield, Beatrice J. Stephenson, P. H. Tordoff, T. R. Wilson, D. S. Young. (Part II): J. R. Achfeld, T. E. Broadbent, D. Brook, A. B. Dick, A. T. A. Fairweather, H. T. Hardy, D. G. Huntly, E. Hyman, D. J. McCandlish, Marjorie Marquis, Kathleen V. Miller, J. Oulton, C. T. Roberts, C. R. Robson, Dorothy E. Rowling, J. F. Scannell, J. L. Sharp, A. H. Snellam, I. S. Stewart, C. L. Summerfield, A. W. Taylor, J. P. Watson, K. B. Wood.
D.P.H.—R. G. Smithson, E. H. Tomlin, Marjorie M. Wilson.
The William Hey Gold Medal and the West Riding Paed Practitioners' Prize has been awarded to W. M. H. Shaw.

The Services

HONORARY PHYSICIAN TO THE KING

Major-General P. S. Mills, C.I.E., I.M.S., has been appointed Honorary Physician to the King.

EFFICIENCY DECORATION OF THE TERRITORIAL ARMY

The King has conferred the Efficiency Decoration of the Territorial Army upon Lieutenant-Colonel and Brevet Colonel L. H. Taylor, Lieutenant-Colonel W. W. Hallchurch, Major E. E. Lightwood, Major P. Hickey, Major J. Cohen, and Major R. S. Creed.

DEATHS IN THE SERVICES

Colonel PERCY CHARLES HUTCHISON STRICKLAND, Madras Medical Service (ret.), died at Clifton, Bristol, on September 4, aged 75. He was born at Kampti, in the Central Provinces, on August 14, 1863, the son of Captain William George Malcolm Strickland of the 49th Madras Infantry. He was educated at Dulwich College and St. Bartholomew's Hospital, and took the M.R.C.S. in 1886, the L.R.C.P. Lond., and L.S.A. in 1887, and also subsequently the D.T.M. at Liverpool in 1912. Entering the Indian Medical Service as surgeon on October 1, 1887, he attained the rank of colonel on May 25, 1914, and retired on August 19, 1920. He served in the Burma Campaign in 1889, and with the Wuntho Field Force, in the Mogaung Column, in 1891. From 1917 to 1919 he was Inspector-General of Civil Hospitals in Burma. He was a member of the British Medical Association for fifty-one years.

Colonel HENRY FRANCIS CLEVELAND, C.I.E., Bombay Medical Service (ret.), died suddenly at Blackheath on September 17, aged 74. He was born on November 30, 1863, at Bombay, and was educated at University College, London, and took the M.R.C.S. Eng., L.R.C.P. Lond., and the L.S.A. in 1888. He entered the Indian Medical Service as surgeon on September 30, 1889, became brevet colonel on January 1, 1911, colonel on October 1, 1918, and retired on October 25, 1922. He served on the North-West Frontier of India in the campaigns of 1897-8; on the Malakand (medal with clasp), and in Tirah (clasp); in the China War of 1900 (medal); and in the war of 1914-19 in Afghanistan and on the North-West Frontier in 1919, when he was mentioned in despatches in the *London Gazette* of August 3, 1920. He was appointed Deputy Director-General of the Indian Medical Service on November 1, 1916, and from October, 1917, to January, 1918, he officiated as Director-General. He received the C.I.E. on January 1, 1918. He was honorary surgeon to the Viceroy of India from 1913 to 1918. His wife was Kathleen, daughter of the late G. Rodway Swinhoe of Swinton, and he had one daughter.

Lieutenant-Colonel RICHARD HARRIS HALL, R.A.M.C. (ret.), died on July 12, aged 75. He was born at Blackrock, County Cork, on May 26, 1863, was educated at Queen's College, Cork, and graduated as M.D., M.Ch., and M.A.O. in the Royal University of Ireland in 1883. Entering the Army as surgeon on May 30, 1885, he became lieutenant-colonel after twenty years' service, and retired on May 26, 1918. He served in Burma in 1887, and received the frontier medal with a clasp.

Lieutenant-Colonel MATTHEW CORRY, I.M.S. (ret.), died at Hove on September 19, aged 64. He was born on November 10, 1873, and was educated at Edinburgh University, where he graduated M.B., C.M. in 1896. He proceeded M.D. in 1911. For a time he acted as demonstrator of anatomy at St. Andrews University. He entered the Indian Medical Service as lieutenant on January 27, 1900, became lieutenant-colonel on July 27, 1919, and retired on November 10, 1928. Most of his service was spent in the Punjab in civil employ, which he entered in May, 1902, serving as plague medical officer and later as civil surgeon. From May, 1917, to August, 1920, he was on military duty, and after his return to civil work in October, 1920, he was appointed lecturer in midwifery and medical jurisprudence in the medical school at Amritsar. He had been a member of the British Medical Association for thirty years.

Medical News

We are asked by the Medical Insurance Agency to inform the profession, many of whom have made urgent inquiries during the past few days of crisis, that no insurance company will accept any risk arising from air bombardment, etc., in accordance with a decision reached many months ago by a unanimous conference of the offices. Presumably before long—possibly even before this appears in print—the Government will announce its plans (as was done in 1914) for covering these risks. Until that happens the M.I.A. has necessarily no useful information to give.

Parliament reassembled on September 28 for a special sitting to consider the European crisis. The House of Lords adjourned immediately. In the House of Commons Mr. Chamberlain reviewed recent negotiations and announced that he had been invited to meet Herr Hitler at Munich on the following day. The House then adjourned till October 3. No emergency legislation was introduced on September 28, and the only question asked concerned compensation for damage by air raids. Sir John Simon replied that the Government was considering a comprehensive scheme.

In our advertisement columns this week applications are invited by the Royal College of Surgeons of Edinburgh for the post of Conservator of the Museum and Director of Postgraduate Studies, tenable for five years with eligibility for reappointment, at an initial salary of £1,000 per annum.

The seventeenth Annual Congress of Anaesthetists, which will be held in New York from October 17 to 21 during the "Congress of Surgeons' Week," will comprise a joint session of the Associated Anaesthetists of the United States and Canada, the International Anaesthesia Research Society, the International College of Anaesthetists, the Eastern Society of Anaesthetists, and the Mid-Western Association of Anaesthetists. An address will be delivered on the life and work of Sir Frederic Hewitt, and special anaesthesia clinics and laboratory demonstrations will be arranged. One meeting will be devoted to current researches in anaesthesia and analgesia, and the newer methods in anaesthetics will be demonstrated.

The August number of *Discovery* contains a review of Professor A. J. Clark's pamphlet, *Patent Medicines*, and articles on nutrition and vitamins. In the June number there was an article by Professor J. A. Ryle on "The History of Research on Digestion and Pernicious Anaemia." *Discovery* is now edited by Mr. C. P. Snow, Ph.D., and in its new form is an attractive and interesting popular scientific periodical.

Arrangements Cancelled

The annual dinner of St. Mary's Hospital Medical School, announced to be held at Claridge's on October 1, has been cancelled; also the special postgraduate course which was to have been held from September 29 to October 2. It has been decided to cancel the arrangements made for this week end by the Charing Cross Hospital Medical School, which included the prize-giving, annual dinner, and postgraduate course. The annual dinner of St. George's Hospital Medical School arranged for October 1 has also been cancelled, and the old students' dinner of St. Thomas's Hospital Medical School, arranged for October 7.

In present circumstances it has been decided to cancel the Health Conference which was to have been held under the joint auspices of the Department of Health for Scotland and the Ministry of Health at the Empire Exhibition in Glasgow on Friday of this week. The two-day conference of the Central Council for Health Education, which was to have preceded it, has also been cancelled.

The conference of the British Health Resorts Association at Torquay, which was to have opened on Friday, has been postponed.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended September 17, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 126 great towns (124 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases ; a blank space denotes disease not notifiable or no return available.

| Disease | 1938 | | | | | 1937 (Corresponding Week) | | | | | 1929-37 (Median Value Corresponding Weeks) | |

* After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Acute Poliomyelitis

Notifications for poliomyelitis in England and Wales were 76, an increase of 3 on the previous week, and in London 7, representing an increase of 2. Notifications of more than one case were reported from: Portsmouth 4, and 2 each from Aberayron, Accrington, Braintree (Rural 1), Hull, Ipswich, Leamington, Leyton, Llandilo, Ruthin, and Veninor. The 7 London cases were distributed thus: Hackney, Hammersmith, Wandsworth, 2 each, Islington 1. During the four-week period ended September 10 the number of cases notified of poliomyelitis and polio-encephalitis was 313 compared with 221 for the previous four-week period and 167 for the corresponding period last year. In Germany during the week ended September 3, 365 cases were reported as against 319 in the previous week. The areas chiefly affected were: Cologne district 112 (89), Wiesbaden district 23 (15), Frankfurt district (Prussia) 15, Württemberg 47 (55), Bavaria 31 (18), Saxony 24 (19). In Holland a decline of poliomyelitis was observed in the week ended September 10; from 67 to 58 for the whole country, and from 37 to 31 in the Province of South Holland. Five cases were reported from the Hague district, 6 in Rotterdam district, and 4 in Waddinxveen district (South Holland).

Enteric Fever

In England and Wales notifications of enteric fever increased from 36 to 45, and deaths in the 126 Great Towns rose during the week from 4 to 5. More than one case was notified in: Coventry 10 (1), London 3 (2)—Stepney 2, Woolwich 1—and 2 each in Liverpool, Preston, and Whitstable.

Diphtheria and Scarlet Fever

Diphtheria continues to increase in prevalence in England and Wales, while a slight decline was noted in Scotland during the week. The chief centres in which increases were recorded are: London 159 (146), Birmingham 36 (31), Easington 18 (0), South Shields 16 (15), Prescott 13 (2), Cardiff 12 (8), Stoke 12 (6), Plymouth 10 (3). A small rise in notifications of scarlet fever in England and Wales, 1,683, as against 1,625, in which London has shared, 131, as against 121, has been recorded for the week. Noteworthy increases were: Sheffield 31 (19), Leeds 36 (32), Nottingham 24 (17), Cardiff 14 (9), Carlisle 13 (7), Portsmouth 13 (11), Heston and Isleworth 10 (5).

Measles and Whooping-cough

Three deaths from measles were recorded in the 126 Great Towns of England and Wales, compared with 5 in the previous week, 2 in London and 1 in Nottingham. In Scotland notifications fell from 37 to 19, the chief centres affected being Glasgow 11 (12), Dundee 4 (6), and Kirkcaldy 3 (3). Of the 8 deaths from whooping-cough in the 126 Great Towns one occurred in each of the following: London, Barnsley, Blackburn, Bradford, Gateshead, Newcastle, Sheffield, Walsall. In Scotland a considerable fall in notifications was recorded; 117 compared with 232, but 4 deaths (all in Glasgow) represented an increase of 1 over the previous week.

Cholera

A report from one of the League of Nations anti-cholera units in China states that in the Hunan Province during the first eight months of 1938 there were 4,080 cases with 1,764 deaths. During June and July 16,805 cases with 6,103 deaths were reported in Eastern Kwantung, chiefly in Chaoyang district 5,063, Lufong 4,454, and Haifong 624. The southern part of the Kwantung Province suffered less, as shown by a decline in the figures for Canton, Macao, and Hong Kong. Cholera has appeared in Inritsu, about 190 miles east of Dairen, and has spread to towns and districts to the north-east. By September 17, 35 cases with 20 deaths had been recorded. In British India the disease continues to decline. In the Central Provinces, which was the chief centre affected, there were reported for the week ended September 17 5,295 cases with 1,794 deaths, compared with 5,486 cases and 2,361 deaths in the previous week.

Plague

The incidence of plague in British India has fallen considerably compared with recent years. The fall was particularly marked in the Central Provinces (12,611 in 1936-7 to 5,477 in 1937-8), and in the United Provinces 10,684 to 5,253, which were the principal foci of the disease, representing 46 per cent. of the total for the whole of India including Burma. In Burma a small increase is recorded, 2,845 compared with 2,503, mainly due to the epidemic of January and February of this year. In Manchuria from May 1 to August 31 a total of 286 cases with 228 deaths was recorded. The areas chiefly affected and in which spread has occurred since the beginning of the autumn are: Ch'angling Prefecture, Kirin Province, 72 cases, 63 deaths; Kuorhlossu Banner, Kirin Province, 52 cases, 42 deaths; K'ai'ung Prefecture, Fengtien Province, 46 cases, 24 deaths.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

THE TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

THE TELEGRAPHIC ADDRESSES are

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitology Westcent, London.

SECRETARY, Medisecra Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúirí na h-Eireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: Bacillus, Dublin; telephone 36250 Dublin).

QUERIES AND ANSWERS

Treatment of Buccal Ulcers

Dr. R. E. ISAAC (Whetstone, N.) writes: I would be grateful for suggestions for treatment in the following case. A married woman, age 32 years, has had ulcers in the mouth for two years. Blood count originally showed a very slight secondary anaemia, but is now normal after treatment with iron, campolon, and anahaemin. All teeth have been extracted. Local treatment already tried includes applications of carbolic acid, copper sulphate, silver nitrate, glycerin, tannic acid, resorcin in glycerin, and mouth washes of all types, of which dettolin gives most relief.

Regression after Psycho-analytical Treatment

"J. D." would like to hear of any experience doctors may have had with persons who have undergone Freudian psycho-analysis and in whom regression has occurred, so that they have lapsed back into their former state.

Wasp Stings

"A. H. D." writes: Can any form of inoculation be given against wasp stings? The case is that of a woman working in a fruit shop, who, if stung by a wasp anywhere, collapses immediately. I have seen her in this state, unconscious, almost pulseless, and with every sign of profound shock. As she is always liable to stings she naturally wishes to know whether anything can be done to render her immune. I would be grateful for any suggestions.

Treatment of Superficial Glossitis

Dr. C. A. HUGHES (Liverpool) writes: In answer to the query of "O. M. N." (*Journal*, September 10, p. 604) I would advise that the surface areas on the tongue or inside the mouth, wherever sore, be dabbed often during the day with pellets of cotton-wool soaked in the following: glycerin boracis, 1 oz.; tinct. myrrhae, 1 drachm; with liq. hydrarg. perchlor. to 2 oz.

Cleaning Slides for Blood Films

Dr. B. R. SANDIFORD (Cairo) writes in reply to "J. S. M." (*Journal*, August 27, p. 480): May I say that there is only one really efficient method of cleaning slides—namely, taking the slide between forceps and roasting it well in the Bunsen flame. The efficacy of this or any other method may be simply tested by observing the ease with which a loopful of water spreads on the slide.

Dr. ALISTAIR FRENCH (Greenford) writes in reply to "J. S. M." (*Journal*, August 27, p. 480): May I suggest a brisk rub with a piece of tissue paper and a spot or two of (methylated) ether. Incidentally, the uses of the latter in the surgery are manifold. (1) It is invaluable for cleaning dirty wounds, being a grease solvent, a vasodilator—thus increasing bleeding and washing dirt out of the wound—and an antiseptic. (2) As a rubber solvent it will remove rubber adhesive plaster, elastic or otherwise, without pain, and prevents dirty sticky marks being left on the skin. (3) It will dissolve the sebaceous grease on the skin, and thus facilitates the treatment of boils, etc., with elastoplast, and increases the rate of absorption of any drug given by inunction (also by its vasodilator effect). (4) It is the best skin sterilizer for use before vaccination or hypodermic injection.

Sensitivity to Sunlight

Dr. IVOR RADNOR (Birmingham) writes: I read with interest the annotation on sensitivity to sunlight in the *Journal* of August 27. Could anyone tell me of any treatment for a person who is very sensitive to solar rays and dare not be exposed to the rays of the sun in the summer?

Treatment of Pruritus Ani

"J. M." writes: I have a patient, a male, who is suffering from pruritus ani, which is quite unaffected by local applications. I have tried injections of novocain without success. I am contemplating the injection of 95 per cent. alcohol, but before undertaking this I would be grateful for any suggestions as to recent successful forms of treatment.

Control of Bulimia

Dr. NORA L. KEEVIL would be grateful for suggestions as to treatment of the following case: A man of 75 who is now in an advanced stage of paralysis agitans has, apart from the usual symptoms, developed a persistent and most distressing feeling of hunger, following an attack of shingles three months ago. Every type of antacid has been tried, as well as glucose D, charcoal, barley sugar, codeine, pilocarpine, atropine, etc., but he is still obliged to eat every carpine, atropine, etc., but he is still obliged to eat every one and a half hours throughout the day, and at least two or three times during the night.

Income Tax

Stock of Materials, Drugs, etc.

"R. B. R." explains that the inspector of taxes dealing with his firm's liability is pressing for an annual valuation of "all materials, drugs, and instruments" belonging to the firm, and asks whether such a request can be enforced.

** So far as the calculation of the year's earnings is concerned the valuation of the stock of drugs, etc., will not affect the result except to the extent to which the valuation varies from year to year. If, for instance, the valuation varies from year to year. If, for instance, the stock goes up by £100 it implies that during the past year £100 more has been deducted as an expense than was incurred in earning the profits of that year, and of course the converse must have occurred if the stock has gone down. If, therefore, our correspondent is in a position to show, or at least to affirm, that the practice stock remains more or less at a constant figure, we think that the inspector of taxes might waive his request, or, alternatively, that he would not be supported therein if "R. B. R." appealed to the Commissioners—local or special—on the point.

LETTERS, NOTES, ETC.

Medical Evidence at Inquests

Dr. J. B. ALEXANDER (London, E.17) writes: The letter of Dr. A. Lankester and Dr. I. J. Davis in the *Journal* of September 10 (p. 596) have stimulated me to record my somewhat similar experience. I had been treating a middle-aged woman for some months for extreme depression. One afternoon I received an urgent call to her house, and found the house full of gas and the patient lying on the scullery floor. The door of the gas oven was open, but the husband had turned off the gas. I sent him to fetch a policeman, opened all the windows and doors, dragged the woman into another room, and administered artificial respiration for nearly half an hour, assisted some of the time by oxygen supplied by the local fire brigade. My efforts, however, were ineffective. The next morning the coroner's officer rang me up for brief particulars of the woman's past and of the circumstances of her death. That is the last I heard of the business. The local press gave a full account of the inquest, at which the policeman took the entire credit for all the efforts at resuscitation. I was not mentioned.

Dr. MEYER J. LANGE (London, S.E.1) also writes: I was resident at a Croydon hospital over a period of two years, during which time I saw a considerable number of patients brought in dead or dying very soon after admission. In the majority of these death was obviously due to natural causes, such as cardiac failure, cerebral haemorrhage, etc. In these cases the house officer concerned, who examined the case and certified death and in addition notified the coroner, was never even requested to attend the inquest. Often the body was removed to a neighbouring institution, where the necropsy was performed by an "outside" medical man. Subsequent information was gleaned from the local newspaper. The only occasions when the house officer was asked to perform the post-mortem examination or attend the inquest were in connexion with accident cases, where death was due to multiple injuries. Night I add that a competent full-time pathologist was attached to the hospital, who was always most willing to give advice and assistance in the post-mortem room.

Blood Transfusion Service

The annual report of the Blood Transfusion Service, 1937, records a considerable increase in the number of calls during the last four months of the year. During this period there were 2,018 calls, comparing with 1,683 for the corresponding months of 1936. An analysis of the net cost per case is of interest. The total figure of eight shillings per case is made up as follows: donors' expenses, 10d.; and sixpence is made up as follows: donors' expenses, 10d.; and salaries and insurance, 2s. 7d.; office rent, lighting, and heating, 4d.; printing, postage, telephones, and telegrams, 1s. 5d.; research work, 2s.; cost of sera, bandages, propyls, and miscellaneous, 1s. 3d. An International Congress, attended by representatives of twenty-two nations, was held at Paris in September-October. Useful contacts were made with foreign delegates, and in several cases an interchange of forms and publications was arranged. Problems of blood transfusion and storage aroused especial interest, but it is stated that little practical information was obtained. The method in vogue in the U.S.S.R. of extracting blood from freshly deceased cadavers was described to the congress; also the technique of extraction from living donors in Spain, where it is the practice to mingle the blood of six different persons in order to "average out" minor individual incompatibilities. The report deprecates the sensational manner in which the subject of blood transfusion is treated by a large section of the lay press. This is said not only to impede recruiting of donors but also to deter friends and relatives of patients from giving consent to the operation. Among captions quoted are "Curate gives health for child," "Blood donor dies in poverty," "Policemen become anaemic through giving blood," and "Saved life—lost job."

Faecal Impaction

"ROBERTO" writes with reference to recent letters on faecal accumulation in the rectum: The injection of an ounce of 10 vol. peroxide of hydrogen, by disintegrating the scybala and by rapid increase in gaseous volume, gives sometimes wondrous relief. *Experto crede.*

KEY TO CURRENT MEDICAL LITERATURE

GENERAL JOURNALS

Bulletin of the Johns Hopkins Hospital

Baltimore vol. 62 June, 1938

*Observations concerning Toxicity, Absorption, and Therapeutic Effect of Sulphanilamide and Certain Related Organic Sulphur-containing Compounds in Experimental Infections in Mice. W. H. Feinstein, E. A. Bliss, E. Ott, and P. H. Long.—p. 565.

*Occurrence of Pharyngeal Infections in Exophthalmic Goitre. John T. King.—p. 593.

Researches on Tetanus: VIII. At what Point in Course of Tetanus does Anti-tetanic Serum save Life? J. J. Abel and W. Chalian.—p. 610.

Sulphanilamide and Related Compounds.—As the result of their experiments the authors of this article conclude that sulphanilamide is from all points of view the most suitable compound for the treatment of haemolytic streptococcal and meningococcal infections in human beings. It is of doubtful value in pneumococcal and staphylococcal infections.

Pharyngeal Infections in Exophthalmic Goitre.—King pleads that the once-popular "infection" theory as to the causation of exophthalmic goitre should not be forgotten. He has never seen the disease cured by tonsillectomy, but believes that this procedure helps to prevent recurrences.

*Anaemia in Pregnancy and Puerperium. E. M. K. Stevenson.—p. 81.

Anaemia in Pregnancy and Puerperium.—This paper records an investigation of one hundred cases of anaemia occurring during pregnancy and the puerperium. The author considers that the existing literature fails to emphasize the frequency and importance of anaemia as a complication of pregnancy and the puerperium. Thirty of the cases were of the "pernicious" type. Expectant treatment of this type of case is dangerous. Cure is brought about by the administration of liver, and maintenance treatment is usually unnecessary. The recognition and treatment of this anaemia in the early stages will save some patients from becoming chronic invalids, and may actually prevent a fatal issue.

Endemic Deaf-dumbness.—Microscopical examination of the temporal bones from three deaf-and-dumb Swiss patients—

being a cretin and two goitrous—showed pathological features affecting almost exclusively the middle ear, with conspicuous increase in the size of the periotic labyrinthine capsule, partial or complete occlusion of the niche of the round window, and other lesions, which are described in detail. The cochlea and internal ear as a whole were little changed, or were normal.

Sclerosis of Pulmonary Artery.—On the basis chiefly of four non-congenital cases recently studied Michaud discusses the pathogenesis of primary sclerosis and of the variety which is superimposed on morbid cardiac or pulmonary conditions. The results of tests of pulmonary function in three cases are described. In one case necropsy revealed a purely fractional dilatation, although clinical, tomographic, and other findings had pointed decidedly to an organic sclerosis.

Lymphogranulomatosis in Basile.—The cases numbered thirty-seven. The localization and mode of spread are analysed and the haematological findings reported. Diagnosis at present must be based on histological examination, repeated in early or doubtful cases. Diagnosis of Hodgkin's disease by exclusion is not justified, and the designation "atypical lymphogranulomatosis" is valueless and confusing.

New Radium Treatment.—The author describes a new method of radium treatment to produce large homogeneous fields of gamma radiation of sufficient intensity with only moderate quantities of radium. Radium is intimately mixed with a heavy metal and formed into plaques of various shapes, according to the part under treatment. It is anticipated that treatment of cancer in various organs will be possible without producing any changes in the skin other than minor reactions, and that no operative treatment will be necessary.

Canned Milk.—It is proved that there is no appreciable loss of vitamin A in canned milk, as it is not possible for oxygen to exercise any influence. The vitamin C is also hardly influenced, though it is slightly less than in fresh milk. The vitamins, however, vary according to whether the milk used is from cows confined to stalls or from those kept on pasture. Sweetened skimmed milk contains practically no vitamin A; this milk is fatless and therefore quite unsuitable for infant feeding. All milks, however, whether fresh or canned, contain less vitamins than breast milk.

- Spirochaetes in Brain in General Paresis in Jamaica.—G. M. Saunders.
- Syphilis in Dependent Mothers.—H. Harrington and L. J. Matschat.

Infectiousness of Semen.—The semen of 144 cases of syphilis was examined for spirochaetes by various methods, and the

organisms were found in fourteen, or 9.7 per cent. In sixty-seven early (less than four years) cases the figures were thirteen, or 19.4 per cent., and in fifty-two late cases they were one, or 1.9 per cent. It is therefore concluded that spirochaetes are present in the semen in about the same frequency as in other body fluids in early syphilis, but that in late syphilis they are very rarely present in the semen. A complete bibliography is appended.

Infection and Treatment of Syphilis.—This article represents a discussion of the relation of persistently positive serum reactions to immunity and the treatment of chronic syphilis. The author comes to the following conclusions, among others: that immunity is acquired only by infection, is of the tissue type, is responsible for clinical latency, and may fail to prevent reinfection or superinfection; that antibody is similar in nature to the agglutinins produced from *B. proteus* in the Rickettsia diseases, is not treponemocidal, may occur in certain normal animals and in some cases of leprosy and malaria owing to the presence of partial antigens or haptens in the organisms producing these diseases; and, finally, that persistent positive serum reactions are not due to "hang-over" of reagin following cure but to persisting infection.

Mapharsen in Latent Syphilis.—Mapharsen is as effective in the treatment of latent syphilis as neoarsphenamine; it is, however, less toxic, a matter of some importance, since many patients with latent syphilis are past the prime of life. It gives better results when combined with bismuth, and the two drugs are more efficient when given concurrently than when given alternately.

- Fluorescence of Salicylic Acid Compounds. M. Dérivé.—p. 374.

Rough Water Supply.—A technical description of the water supply of Rouen, with an account of recent extensions and improvements. The water is obtained from two natural sources in the chalk formation, and is filtered, chlorinated, and stored in distributing reservoirs. Statistical tables from 1900 to 1937 are used to show the reduction in typhoid since these works were undertaken; also the favourable position of Rouen in this respect as compared with other Continental cities.

New Cause of Lead Poisoning.—Arsenate of lead is supplied largely to agriculturists in Puy-de-Dôme for the purpose of spraying fruit trees, vines, etc. Hands, face, and especially lips and moustaches become contaminated and are not cleaned by ordinary washing. The toxicity of this compound of lead is not appreciated by the workers, hence plumbism is prevalent. It is recommended that arsenate of aluminium (equally effective) be used instead.

Resistance of Bacilli in Water.—The author describes a series of experiments to determine the length of life of various pathogenic bacilli in waters of different qualities—pure, saline, foul, infected with saprophytes, etc.—also the effect of light and temperature. The bacilli used were those of typhoid, paratyphoid A and B, Shiga, Koch, and Loefler, the growth of the last two being very feeble.

Hyperparathyroidism Resembling Paget's Disease.—Three cases of hyperparathyroidism with radiological appearances resembling Paget's disease are described. In two the appearance was thought merely to simulate Paget's disease; in the third it was suggested that the two diseases coexisted. It was concluded that there was no evidence that the two diseases were related conditions.

Liver Powder in Amyloid Disease.—Thirteen children with secondary amyloid disease, were treated with a crude whole liver powder; four died, one was unimproved, six were cured, and two were improved. In a control series of sixty-eight cases not receiving liver all died within two years. The cure of the amyloid symptoms is unrelated to the cure of the initial infection.

Infarction of Heart.—A detailed account of the sequelae in 300 cases of coronary thrombosis is given. Congestive cardiac failure was the main cause of death, and occurred in some degree in 55 per cent of cases. Shock and syncope was the next commonest cause. Attention is drawn to the frequency of peripheral thrombosis, which accounts for many incidents attributed to embolism. The morbid anatomy of the cases is discussed in detail. In this series, as in others, the left coronary artery was most often affected.

- Early Cardiac Decompensation in Traumatic Arteriovenous Aneurysms. J. M. Mason, G. S. Graham, and J. D. Bush.—p. 1029.

Adrenal Cortical Tumours.—This is an analysis of seven cases operated upon without fatality. The value of post-operative treatment to anticipate adrenal insufficiency is emphasized.

sized, and is essential if a low mortality rate is to be secured. The variations in the clinical picture occurring with sex and age are well described, as are the difficulties of differential diagnosis from similar syndromes produced by hyperplasia of the adrenals, or by ovarian tumours or intracranial lesions. The close parallel presented to Cushing's syndrome in certain cases and the fact that the treatment of this condition is little more than palliative lead the authors to conclude that in suspected cases of pituitary basophilism the adrenals should always be explored, since a readily removable tumour may be disclosed.

Hypertension.—A review of the experimental methods of producing hypertension is given, and an attempt is made to correlate the experimental findings with the disease process in the human. The selection of suitable cases for operation is discussed, with a preliminary note on the use of cyanates in treatment.

Varicose Veins.—This is an important paper in which the value of the differential tourniquet test in localizing the site of valvular incompetence is described and well illustrated in a series showing insufficiency at various levels. The types of operation suitable to the different cases and the value of post-operative sclerosing injections are discussed.

New Trypanocidal Substances.—This is a valuable paper analysing the relation between the trypanocidal activity and chemical constitution of a new series of experimental trypanocidal substances.

Resistance to Guanidine and Diamidine Compounds.—Resistance is only acquired slowly, and differs from resistance produced by arsenicals, antimony, acriflavine, or Bayer 205. Guanidine- and diamine-resistant trypanosomes are sensitive to aromatic arsenicals and to Bayer 205, and vice versa.

Archives d'Ophthalmologie

Paris vol. 2 July, 1938

- Observations on Retinoglioma in Child of 16 Months. R. Arnaud and L. Calmettes.—p. 593.
- Palpebral Manifestations of Tertiary Syphilis. G. Renard and P. Halbron.—p. 599.
- How to Achieve Rational and Efficacious Social Prophylaxis against Trachoma in Indo-China and more especially in Tonkin. P. Keller.—p. 606.

Palpebral Syphilis.—Syphilis rarely attacks the lids. A gumma is most frequently seen; it is commoner in women, and appears at least three years after the primary infection. Gummatous ulceration may be confused with ulcerating dacryocystitis, Meibomian cyst formation, or epithelioma. A

nodular gummatous tarsitis resembles a tarsal cyst. The marginal gumma presents appearances similar to those of ulcerative blepharitis. In all cases the rapid effect of specific treatment assists in the diagnosis.

Surgical Treatment of Corneal Affections. R. Rubrecht.—p. 714.

After-cataract.—A small limbal puncture and counter-puncture are made with a Graefe knife. Through the temporal incision a cystitome detaches and draws the nasal half of the capsule to the centre of the pupil. Forceps passed through the nasal incision grasp the freed part of the capsule, detach the remainder, and draw the whole out of the eye.

Experimental Contributions to Gold Therapy in Tuberculosis: III, Histological Investigations on the Deposition of Gold in the Organs of Rabbits treated with Gold. IV, Specific and Non-specific Blood Investigations in the Gold Treatment of Tuberculosis. St. J. Leitner.—p. 626.

Gold Therapy.—These experiments support the view that the beneficial effect of gold in pulmonary tuberculosis is due to stimulation of the reticulo-endothelial system. The white blood count was found to be the most reliable index of the effect of gold therapy. Eosinophilia is a most sensitive sign of susceptibility to gold.

Central Pathway in Man of Vasomotor Response to Pain. D. G. Marquis and D. J. Williams.—p. 203.
Vasomotor Control of Cerebral Vessels. H. S. Forbes and S. S. Cobb.—p. 221.

Headache.—In this paper the author describes the results of a clinical study of headache in cases of intracranial tumour. The incidence of the symptom, the distribution of the pain, and its relation to the intracranial pressure are discussed. Clinical experimental observations designed to determine the mechanism of the headache are described. It is concluded that the dura mater is not the sensitive structure which is responsible, but that the headache is caused by an abnormal state of tension in the walls of the cerebral blood vessels.

Gliomatosis Cerebri.—Three cases of diffuse new growth of neuroglial cells throughout wide areas of the cerebral hemispheres are described. Clinically they were characterized by a long history of epilepsy followed by mental symptoms and increased intracranial pressure. The pathological process was considered as primarily a blastomatous malformation closely related on the one hand to Von Recklinghausen's disease, and on the other to diffuse gliomas of the pons, thalamus, and optic nerve.

Vasomotor Control of Cerebral Blood Vessels.—The literature on this subject is reviewed and some original experimental observations with a cranial window and microscope in cats, dogs, and monkeys are recorded. It is concluded that there is now substantial agreement among workers in this

field to the effect that while there is evidence of vaso-constrictor and vasodilator nerve fibres in the cerebral blood vessels, chemical factors, especially carbon dioxide, play a major part in the regulation of the cerebral blood flow.

Children with Defective Vision: In Need or Not of Sight-saving Classes. R. A. Kaz.—p. 486.

Rhinosporidiosis.—Due to a parasite causing an exfoliative non-infiltrating granuloma, this lesion usually occurs on the nose, but has been noted in the lacrimal sac and on the conjunctiva. A case is described where, originally on the conjunctiva, a recurrence appeared two and a half years after excision of the primary trouble. The lesion was excised and cauterized and 2 per cent. antimony tartrate drops were prescribed. A description and illustrations of the microscopic characteristics are added.

Objectives of Industrial Hygiene. F. M. R. Bulmer.—p. 345.

Staphylococcal Food Poisoning.—In the former of these groups an investigation was made of a small outbreak (five families) of food poisoning due to *Staph. aureus*, the vehicle being cream and custard-filled pastry. The symptoms were gastric distress, vomiting, and diarrhoea. The organism was recovered from gastric contents and faeces of patients, from material and products of the bakery, and from the nose and throat (but not urine and faeces) of certain employees. Tests for typhoid and paratyphoid were all negative. In the second group of cases (nine families) the onset was more acute and suggested intoxication rather than bacterial invasion. *Staph. albus* as well as *Staph. aureus* was found. It is suggested that the toxicity of these organisms is increased by growth in a starch medium.

 Unified Theory of Aetiology of Shock. N. W. Roome.—p. 237.

Sodium Isoamyl Ethyl Thiobarbiturate.—The anaesthetic efficiency of this compound, or sodium thio-ethylamyl, has been studied experimentally on rats and cats, and compared with that of sodium amylal, of which it is the sulphur derivative. Sodium thio-ethylamyl shows a greater anaesthetic range of safety and more consistency in its effects than its non-sulphurous homologue. A study of poisonous doses has shown the value of atropine and ephedrine, as well as that of the usual anaesthetics. Spasm of the larynx has been found to be of importance in the causation of asphyxia as well as central depression, and is effectively combated by intubation.

Sodium Thio-ethylamyl Anaesthesia.—A preliminary series of 100 administrations has been carried out with this newly introduced anaesthetic. Cases were selected, and in general it was confined to those requiring only brief anaesthesia. In general the results were comparable to those of other short-acting barbiturates given intravenously. A note of caution is sounded both as to the conclusions to be drawn from this report and as to the intravenous use of barbiturates in general.

Cross-infection by Gas Machines.—The possibility of the transmission of bacteria by gas machines has been investigated. A water filter is described, designed to be fitted into the expiratory side of circuit breathing apparatus, and which is claimed to prevent the passage of bacteria and therefore the contamination of the machine.

Reducing Agents.—There are differences in the power of reduction of various chemical groups, particularly the "trans"

† In this periodical the language in which each paper is presented is indicated as follows: English (Eng.); German (Ger.).

situated OH group in various types of keto- and aldo-hexoses, the endiol groups in ascorbic acid, the $\text{HN}=\text{C}$ group in creatine and creatinine, the SH group in glutathione, and the CO group in pyruvic acid.

Brain Metabolism in Uremia.—Experimental nephrectomy, or the injection of uranium nitrate or potassium chromide, causes true uraemia in dogs. In such cases the tissue respiration and glycolysis, particularly aerobic glycolysis, increase. With respiration glycolysis is arrested and the "Meyerhof quotient" decreases. The results show an increase in the metabolism of the brain in true uraemia.

 True Sarcoma of Kidney in Adult. P. Macquet and P. Decoux.—p. 528.
 Enormous Rounded Calculus of Renal Pelvis. P. Macquet and P. Decoux.—p. 532

Transurethral Resection.—This is a sane consideration of the subject. Four post-prostatectomy resections were performed for persistent fistula or for incontinence due to diaphragm formation. Eleven resections for prostatic carcinoma entailed three deaths (27.7 per cent.). Thirty-six resections were performed for bladder-neck dysectasia—twenty-seven with closed bladder (no mortality) and nine after cystostomy—the total mortality being 2.7 per cent. The results were excellent in eleven cases, and also in a twelfth, which, however, called for a second resection. In the others the result was less good—residual urine minimal, but persistence of marked pollakiuria, pyuria, cystitis, or dysuria.

In the cases of resection after cystostomy, cystostomy had been performed in preparation for resection (an indwelling catheter being inadequate), or else resection was done to close a hypogastric fistula. There were thirty-nine resections for prostatic adenomas (twenty-six with closed bladder, thirteen after cystostomy) with one death (mortality 2.5 per cent.). This is notable in view of the numerous cases where resection was preferred to enucleation because of the patient's poor condition. The main indications for resection are certain early prostatic carcinomas, bladder-neck dysectasia, and small prostatic adenomata, especially when the general condition is poor.

Coffey's Operation for Vesical Exstrophy.—The author concludes that the establishment of a mechanical barrier or competent valve between the urinary tract and the colon is possible with an anatomically and functionally healthy ureter. Such a mechanical barrier is not necessarily a bacterial one. But when the ureter is inert, dilated, and congenitally deformed complete valvular competence is only conjectural. Under these conditions the uretero-colic anastomosis does not resist retrograde pressure, and there is a tendency to the phenomenon of ureteral reflux with all its consequences.

One and a Half Years' Experience in Employment of 220 Kilovolt X-Ray Therapy with Heavy Filter: Report on Seven Cases of Carcinoma of Bladder. R. H. Lafferty and C. C. Phillips.—p. 107.

Intestinal and Peritoneal Tuberculosis.—X-ray therapy is particularly indicated in the hyperplastic and simple proliferative forms, and the best results are obtained from early treatment in the ascitic forms of tuberculous peritonitis. Light therapy, both natural and artificial, gives good results in practically all forms of peritoneal and intestinal tuberculosis. The patients are not critically ill.

Remissions in Schizophrenia.—In 267 schizophrenics followed for about three years, Brinck finds 111 total and good social recoveries. The figures obtained with continuous narcosis are distinctly better than those without. He also attributes a favourable influence to discharge from hospital as early as possible.

Homosexuality.—Lang brings further figures in support of his theory that a great number of homosexuals are so by virtue of a genetic factor.

Zeitschrift für Infektionskrankheiten, parasitäre Krankheiten und Hygiene der Haustiere

Berlin vol. 52 February 28, 1938

- Intramuscular Cysts in Moose. R. Wetzel and K. Eniak.—p. 23.

Results of Research on Practical Utility of Formol-vaccine against Contagious Abortion of Cattle. F. Kress.—p. 316.
Laryngeal Cancer in Horse. H. Wilmes.—p. 328.

Brucellosis.—The author reveals the epidemiological characters of the three chief types of Brucella—namely, *Brucella melitensis* (Bruce), *Br. abortus* (Bang), and *Br. suis* (Traum)—especially in regard to geographical distribution, frequency, and the kind of animal affected. Sources, types, and modes of cross-infection are then discussed in considerable detail, and the statement is made that contact infection is more important than milk infection. The article concludes with a scheme for prophylaxis and general control of the disease.

*However Humble the Home — the Lordly
Luxury and Caressing Comfort of the Staples
Mattress is yours by right — for the price
is now within your reach.*

*The Pride of Possession of a Staples Mattress
on your own bed is a purely private and per-
sonal affair, but a Staples Mattress in your
guest's room is a matter of deep interest and
of soft inducement to your friends — tell them.*

STAPLES

"The finest Mattress made"

★A Capsule a day from October to May

Prescribe Adexolin — the
rationally balanced concentrates
of vitamins A and D — throughout
the winter months. Adexolin builds up
a powerful resistance to colds, bronchitis,
influenza, and other seasonal infections. For
susceptible patients the treatment should be
started as early as possible. One Adexolin
Capsule a day (or 20 drops of Adexolin Liquid)

is an effective prophylactic
dose for adults and older children.
For infants, 2 drops of the liquid
should be added to every bottle feed.
Each 3 m Adexolin Capsule is equal in vitamins A
and D to 10 cc. of medicinal cod-liver oil. Each cc. of
liquid to that in 20 cc. of medicinal cod-liver oil.
Capsules: 25, 2/9; 100, 8/6; 500, 30/6; 1,000, 56/-.
Liquid: 1-oz. phials with dropper, 2/6; 2-oz. bottles,
7/6; 4-oz., 12/6; 8-oz., 22/6.

Prices (not applicable in Eire) are subject to usual professional discount

THROMBIN-COAGULANT-MAW DRESSINGS HAVE PROVED THEIR EFFICIENCY!

In the short time they have been on the market, Maw's T.C.M. Dressings have achieved remarkable success. Members of the profession who have used them have been impressed by the rapidity with which coagulation is achieved and numerous instances are recorded of severe haemorrhage being checked almost instantly. T.C.M. Dressings are treated with Thrombin-Coagulant-Maw, a preparation of natural Thrombin which accelerates blood coagulation and causes clotting within 5-15 seconds. They are supplied sterile, in sealed drums, ready for immediate use, and the series consists of special Lint Squares suitable for most purposes. Special T.C.M. Dressings can be supplied when required.

They cost only a trifle more than ordinary Dressings and are well worth the extra charge. We ask you to give them a fair trial, for we are confident that you will be satisfied with the results.

Take THE BURBERRY With You

Then, if the bright morning
does turn out to be a
drenching afternoon, or the
warm breeze change to a
biting Nor'-east wind,
you're certain of being dry
and comfortable.

Under its protective cover
there is comforting warmth
on cold days; complete
security from penetrating
rain; airy light freedom on
the closest day.

The Burberry, therefore,
has the virtues of three
coats in one:—

DUST-COAT for hot days,
WEATHERPROOF for wet,
OVERCOAT when it's cold.

Patterns, prices and illustrated
models on mention of the
"British Medical Journal."

BURBERRYS LTD.
HAYMARKET, LONDON, S.W.1

Experienced Radiologists Will Marvel...

...at the surprising amount
of useful X-ray energy
packed in so small a unit
as the inexpensive new
VICTOR Model F-3.

While it is the newest thing
in X-ray, the F-3 is new only
in refinements that make
for greater power, for
greater convenience in use.
The experience gained in
making hundreds of the
original Model F showed
us where even that world-
famous design might be
improved.

So here is the F-3 with
3.2 times more radiographic
power for even shorter ex-

posures. Kilovoltage is now
variable for optional tech-
niques. And for those who
wish to use the unit
alternately as portable and
mobile X-ray equipment, a
revolutionary new tube
stand has been provided.
Despite all this, the interest-
ingly low price remains
unchanged.

For practical, efficient and
convenient portable and
mobile X-ray service, the
new, more powerful F-3 is
worthy of your fullest con-
sideration. Your written
request will bring you full
particulars, or a demonstra-
tion, without obligation.

This wool is very different

Wool with lower grades before spinning, you would realize how great a difference there must be in the comfort of garments made from the one as against the others. The fleecy white St. Wolstan Wool which is extra soft, very strong and of long staple is a delight to the eye and to the touch. This wool is transformed into handsome garments for your comfort and satisfaction. Ask your hosiery to show you Two Steeples No. 83 Socks made in a shade for every suit.

Two Steeples No. 83 Socks

No. 83 Socks, 4/6 per pair. No. 72, a lighter weight, 3/6 per pair. St. Wolstan Wool Underwear from 12/6 per garment. Dacrona Underwear from 8/6 per garment. Also Quality Knitted Hacking Sweaters, Waistcoats, Golf Hose, etc.

Pattern booklet of socks and underwear sent on request to Dept. 4, Two Steeples Ltd., Wigston, Leicestershire.

Made in Leicestershire,
famous for its hunting
and stockings.

WARM, DRY BEDS FOR OPERATION AND ACCIDENT CASES

In cases of sudden emergency and for everyday use, the "Thermega" Electrically-Heated Blanket is invaluable for providing warm, damp-free beds. Hospitals and Nursing Homes throughout the country use "Thermega." It is the one proven remedy for driving out dampness and ensuring warm beds at the turn of a switch.

The "Thermega" Electric Pad for local application is ideal for relief of pain and for replacing hot water bottles.

At all good stores, chemists, electricians; or from Thermega Limited, 51/53, Victoria Street, London, S.W.1.

'Thermega'
Electrically Heated
BLANKETS & PADS

Blankets from 3 gns. Pads from 31/6. 3-Temperature Blankets for medical use, £8 10s. Single-heat Blanket, specially strengthened from £4 4s. Various sizes and prices on application.

Insist on "Thermega." It is vital that these appliances should be made by experienced manufacturers.

Two NEW Diagnostic SETS

THE GLYNDE containing:
May Ophthalmoscope, with illuminated dial;
Friston Auriscope, with three bakelite Specula;
Duplay Nasal Speculum; Bent Arm Throat Lamp;

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNENT, M.D., M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, and X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, near EXETER,

NEW LODGE CLINIC, WINDSOR FOREST

This Clinic was founded in 1921 in order to provide for the scientific investigation and treatment of disease by a "team" of physicians and specialists.
All forms of non-infectious medical cases are admitted, special attention being paid to disorders of digestion and metabolism, arthritis, anaemias, asthma, heart and kidney disease, and functional and organic nervous disorders.
Particulars can be obtained on application to the Secretary, New Lodge Clinic, Windsor Forest, Berks.
Telephone: 181 and 182 Windfield Row.

CRICHTON ROYAL, DUMFRIES

FOR NERVOUS AND MENTAL DISORDERS.

This Hospital has every facility for complete investigation of the above conditions, and provides all forms of modern treatment including psychotherapy, physiotherapy, occupational and recreational therapy. Cases of alcoholism and drug addiction are admitted. The Physiotherapy Department has separate units fully equipped for X-ray work, heliotherapy, short-wave therapy, electro-therapy, and hydrotherapy (swimming bath, prolonged baths, Scotch and Vichy douches, Plombières treatment, electric and Turkish bath cabinets, etc.). There is a fully equipped gymnasium under qualified instructors. Facilities are provided under special recreational therapists for all indoor and outdoor games, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens.

The Hospital has its own Cinema, Library and Hairdressing Saloon. Terms include regular motor drives. Private rooms, suites, or villas are available and special nurses can be provided.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country and include an extensive farm (F.T. herd), gardens and orchards.
As the Hospital is well endowed terms are exceptionally moderate, e.g. First Department, 3 to 30 guineas per week; Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For prospectus, necessary forms, and further information apply to:
Physician Superintendent, P. K. McCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law.

BOROUGH OF WORTHING.
DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited for the above appointment from duly registered medical practitioners possessing a diploma in Sanitary Science, Public Health or State Medicine. Salary £650 per annum, rising by annual increments of £25 to a maximum of £700 per annum, and a motor-car allowance of £50 per annum. Terms and conditions of appointment and forms of application will be supplied on receipt of a stamped and addressed foolscap envelope.

Applications, with not more than three recent testimonials, must be received by the undersigned not later than October 14th, 1938.

Town Hall, J. KENNEDY ALLERTON,
Worthing. Town Clerk.
October 1st, 1938.

MIDDLESBROUGH EDUCATION COM- MITTEE.

APPOINTMENT OF SENIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified men for the post of Senior Assistant School Medical Officer in connection with the Medical Inspection and Treatment of School Children and such other duties as may be required by the Education Committee. The person appointed will be responsible to the School Medical Officer.

Commencing salary £500 per annum (provided the candidate has had not less than three years' post-graduate experience) rising by annual increments of £25 to £700 per annum. Previous experience as an Assistant School Medical Officer shall be reckoned in calculating the appropriate commencing salary.

The successful candidate will be required to devote his whole time to the duties of the office. The appointment will be subject to two calendar months' notice on either side, such notice to date from the last day of any calendar month.

Applications should be sent to the Education Committee of School Medical Inspection, and preference will be given to candidates who have had experience of Refraction work and in the work of School Clinics and who are recognized by the Board of Education in connection with certification under the Mental Deficiency and Other Acts.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the successful candidate passing a medical examination to the satisfaction of the Medical Officer of Health.

Forms of application may be obtained from the Director of Education and these should be addressed to the Director of Education, Education Offices, Middlesbrough, not later than Saturday, October 15th, 1938.

Canvassing in any form will be disqualify.

PRESTON KITCHEN.

Town Clerk's Office. Town Clerk.

Middlesbrough.

September 26th, 1938.

NEW ZEALAND
DEPARTMENT OF HEALTH, WELLINGTON.

APPOINTMENT OF SCHOOL MEDICAL OFFICERS.

Applications are invited from duly qualified and registered medical practitioners (women) for the above appointments. Candidates must possess a registrable qualification in New Zealand and should have had at least two years' experience in the practice of their profession. They should be under 40 years of age. Salary scale £515 per annum, and thereafter by annual increments of £50 to £665 per annum, with prospects of an ultimate maximum of £715 per annum. The commencing salary may be at any point within the scale, according to age and experience.

The duties include the routine medical inspection of school children, addresses in the children, and periodic lectures to teachers, parents, and the general public, and the inspection and report on school buildings in regard to overcrowding, cleanliness, sanitation, heating, and ventilation.

Successful applicants will be required to commence duty in New Zealand in February, 1939. Reasonable costs of transport to New Zealand will be paid.

Applications close on October 15th, 1938, with the High Commissioner for New Zealand, 415, Strand, London, W.C.2, from whom printed particulars giving the terms of appointment may be obtained.

GENERAL POST OFFICE

HEADQUARTERS MEDICAL BRANCH.
(FEMALE STAFF.)

There will shortly be a vacancy for an ASSISTANT WOMAN MEDICAL OFFICER in the Headquarters Medical Branch. The appointment will be pensionable, and will carry a salary commencing at £100 per annum and rising by annual increments of £25 to £150 a year. The rates of salary are liable to review.

Each candidate must be a fully qualified medical practitioner, a natural-born British subject, and the child of a person who is, or was at the time of death, a British subject. Candidates must also be unmarried, or widows. Preference will be given to candidates under 30 who have held one or more Hospital appointments. The successful candidate will not be allowed to engage in private practice in addition to her official duties.

Applications, stating qualifications, age, etc., with copies of any recent testimonials, should be sent to the Chief Medical Officer of General Post Office, London, E.C.1, not later than October 31st, 1938.

Political influence should not be sought in support of applications; it would prejudice rather than assist the candidature.

The Female Medical Staff at Headquarters consists of a senior Woman Medical Officer and five Assistant Women Medical Officers. Information as to the duties can be obtained from the Chief Medical Officer.

Candidates may be required to attend for personal interview in London at their own expense.

COUNTY OF SOMERSET.

APPOINTMENTS OF MEDICAL OFFICER OF HEALTH FOR THE URBAN DISTRICTS OF FROME AND KEYNSHAM AND THE RURAL DISTRICTS OF FROME AND BATHAVON, AND ASSISTANT COUNTY MEDICAL OFFICER.

Applications are invited from duly qualified Medical Practitioners who are registered in the Medical Register as holders of diplomas in Sanitary Science, Public Health or State Medicine for the above appointments which it is intended shall be held by the same person.

The duties as Assistant County Medical Officer will include school medical inspection and venereal disease work.

The officer appointed will be required to devote his whole time to the duties of the above-mentioned appointments, and will be restricted from engaging in private practice as a medical practitioner. He will be required to perform all the duties prescribed by statute or regulation and such other duties as may from time to time be assigned to him by the County Council.

The aggregate commencing salary will be £600, rising by annual increments of £25 to £600 a year.

Travelling allowance for the use of the officer's motor-car will be paid in accordance with the County scale, and office accommodation and clerical assistance will be provided.

The successful candidate, who must pass satisfactorily a medical examination, will be required to reside in or near the City of Bath.

Applications, stating age, qualifications, diplomas and experience, must be accompanied by copies of not more than three recent testimonials, and must be sent to the Clerk of the County Council, County Hall, Taunton, so as to reach him not later than October 10th 1938, in envelopes endorsed "District Medical Officer."

Further particulars and conditions of appointment may be obtained from the Clerk of the County Council, on receipt of a stamped addressed foolscap envelope.

Canvassing, directly or indirectly, will be deemed a disqualification.

HAROLD KING.

Clerk of the Somerset County Council.

H. J. ALLARD,

Clerk to the Frome Urban District Council.

W. B. KENT,

Clerk to the Frome Rural District Council.

GEORGE R. ASHTON,

Clerk to the Keynsham Urban District Council.

R. H. WHITTINGTON,

Clerk to the Bathavon Rural District Council.

September 22nd, 1938.

COUNTY BOROUGH OF HALIFAX.

THE HALIFAX GENERAL HOSPITAL.
(1405 Beds.)JUNIOR RESIDENT MEDICAL OFFICERS
(Male).

Applications are invited from duly qualified registered Medical Practitioners for the above appointments. Two are required, one for obstetrical and one for medical duties.

Salary £250 per annum or more according to experience, together with board, residence, and laundry. The appointments are for a term not exceeding twelve months and are not renewable.

Forms of application and conditions of appointment can be obtained from the Medical Officer of Health, Powell Street, Halifax.

Completed applications, together with copies of not more than three recent testimonials, endorsed "Junior Resident Medical Officers," must be forwarded to the undersigned as early as possible.

Canvassing, either directly or indirectly, will be a disqualification.

The Council has not adopted a superannuation scheme.

The Town Hall, PERCY SAUNDERS.

Halifax. Town Clerk.

September 20th, 1938.

CITY OF PORTSMOUTH.

TEMPORARY AIR RAID PRECAUTIONS MEDICAL OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from registered medical practitioners for the post of Temporary Air Raid Precautions Medical Officer and Assistant Medical Officer of Health for a period not exceeding one year in the first place, at a salary of £500 per annum. The duties of the appointment will be whole time, under the direction of the Medical Officer of Health, and will be concerned mainly with the teaching of first aid and with the training of the First Aid and Medical Section of the Air Raid Precautions Services. Preference will be given to candidates who have had experience in Air Raid Precautions work and in training in first aid.

Forms of application, giving particulars of the appointment, may be obtained from and should be returned to the Medical Officer of Health, the Guildhall, Portsmouth, not later than 10 a.m. on Friday, October 7th, 1938.

The Guildhall, F. J. SPARKS,

Portsmouth. Town Clerk.

September 20th, 1938.

CITY OF LEEDS.

ASSISTANT CLINICAL TUBERCULOSIS OFFICER.

Applications are invited for the post of Assistant Clinical Tuberculosis Officer. Applicants should be duly qualified and registered medical practitioners, and must have had not less than three years' postgraduate experience, including experience in general medicine, surgery, and radiology, and in the treatment of tuberculosis at a dispensary or in a hospital, sanatorium or other institution reserved for such cases. Preference will be given to candidates with experience in the treatment of non-pulmonary tuberculosis. The possession of a D.P.H., though not essential, would be considered an additional qualification. The present grading scheme of the Corporation provides for a commencing salary of £500-£600 per annum according to qualifications and experience, with annual increments of £25, subject to satisfactory service, to the maximum of £700 per annum. The first increment will take effect on April 1st following the completion of twelve months' service.

The person appointed will be required to pass a medical examination and contribute to the Superannuation Fund, established under the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on a form to be obtained from the undersigned, together with copies of three recent testimonials, and endorsed "Tuberculosis Officer," must be received at the Health Department, 12, Market Buildings, Vicar Lane, Leeds, 1, not later than 10 a.m. on Saturday, October 15th, 1938. Canvassing in any form, either directly or indirectly, will be a disqualification.

J. JOINSTONE JERVIS,
Medical Officer of Health.

CITY OF LEICESTER.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (FEMALE).

September 20th, 1938.

KENT COUNTY COUNCIL.

SENIOR RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Senior Resident Assistant Medical Officer at the County Hospital, Pembury (620 beds).

The salary for the appointment is £350 a year, rising by £25 a year to £450 a year, together with residential emoluments which are valued at £120 a year.

Applicants must have had experience in Surgery. Forms of application can be obtained from the Public Assistance Officer, Tonbridge Road, Maidstone, to whom applications must be sent by stone, 10 a.m. on Monday, October 10th, 1938.

W. L. PLATTS, Clerk of the County Council.
Sessions House, Maidstone.
September 23rd, 1938.

COUNTY COUNCIL OF DURHAM.

EDUCATION DEPARTMENT.

ASSISTANT SCHOOL MEDICAL OFFICERS.

The County Education Committee invite applications for the posts of Two Assistant School Medical Officers (women) to act under the School Medical Officer in connection with the inspection of school children and such other duties as may be required by the Education Committee.

Commencing salary in each case £500 per annum (provided the candidate has had not less than three years' postgraduate experience), rising by annual increments of £25 to £700 per annum, together with travelling expenses according to the County Scale. The successful candidates will be required to devote their whole time to the duties of the office, and reside in or near the districts to which they will be attached at places to be approved by the Education Committee. The appointments will be subject to three calendar months' notice on either side, expiring on the last day of any calendar month.

Applicants must have had experience in the work of school medical inspection, and preference will be given to candidates who

(a) have had experience in the work of School Clinics,

(b) have been accustomed to make special reports on Mentally Defective, Physically Defective, Epileptic, and other Defective Children.

The possession of a Diploma in Public Health is desirable though not essential.

Canvassing, directly or indirectly, is prohibited and will disqualify.

A deduction of 5 per cent. will be made from the salary in each case in accordance with the Local Government and Other Officers' Superannuation Act, 1922, and the appointments will be subject to the candidates passing the medical examination in connection therewith.

Form of application, to be returned not later than Saturday, October 8th, 1938, will be supplied by the Director of Education, Shire Hall, Durham, on receipt of a stamped addressed foolscap envelope.

THOS. B. TILLEY,
Director of Education.
September 19th, 1938.

COUNTY BOROUGH OF BIRKENHEAD.

DEPARTMENT OF THE MEDICAL OFFICER OF HEALTH.

BIRKENHEAD MUNICIPAL HOSPITAL (560 Beds.)

SENIOR RESIDENT MEDICAL OFFICER.

Applications are invited for the above appointment at the Birkenhead Municipal Hospital.

Candidates must be male, unmarried, and duly qualified registered medical practitioners. As the duties are almost entirely of a medical nature preference will be given to candidates who have obtained higher qualifications in medicine and who have had previous medical experience at either a Voluntary or Municipal Hospital.

The appointed candidate will be a member of the staff of the Medical Officer of Health.

The remuneration attached to the appointment will be £350 per annum, rising by annual increments of £25 to a maximum of £450 per annum, together with board, residence, laundry, etc.

The appointment is subject to the Local Government and Other Officers' Superannuation Act, 1922, and is determinable by three calendar months' notice on either side.

Forms of application and further particulars relating to this appointment can be obtained from Dr. D. Morley Mathieson, Medical Officer of Health, 9, Hamilton Square, Birkenhead.

Canvassing, directly or indirectly, will disqualify the applicant.

Applications, endorsed "Senior Resident Medical Officer," should reach the undersigned not later than Saturday, October 22nd, 1938.

E. W. TAME, Town Clerk.
Birkenhead.

PARK HOSPITAL, DAVYHULME, near Manchester.

APPOINTMENT OF ASSISTANT RESIDENT MEDICAL OFFICERS.

Applications are invited from registered Medical Practitioners for the appointments of Assistant Resident Medical Officers at the above Hospital. Candidates must be unmarried.

Salary £300 per annum, together with the usual residential allowances.

One Resident Medical Officer to be attached to the Obstetrical and Gynaecological and Surgical Unit; and the other to the Medical, and Ear, Nose and Throat Unit.

The appointments will, in the first instance, be for a period of six months, the successful applicants being eligible for reappointment for a further period of six months at the end of that period.

The Hospital comprises 500 beds for acute cases, is fully equipped in every respect, and is recognised as a complete Training School for Nurses.

The appointments will be terminable by one month's notice on either side.

Forms of application may be obtained from the County Medical Officer of Health, Hospital and Medical Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded so as to be received not later than Saturday, October 15th, 1938.

County Offices, Preston.
GEORGE EHLERTON, Clerk of the County Council.
September 26th, 1938.

LANCASHIRE COUNTY COUNCIL

PUBLIC ASSISTANCE COMMITTEE.

LAKE HOSPITAL, ASHTON-UNDER-LYNE, Near Manchester.

APPOINTMENT OF RESIDENT OBSTETRICAL OFFICER.

Applications are invited for the appointment of a Resident Obstetrical Officer at the Lake Hospital, Ashton-under-Lyne, near Manchester (500 beds—approximately 600 births per year).

Applicants must hold the Diploma of the College of Obstetricians and Gynaecologists or a diploma of similar standing, and preference will be given to applicants who have held a responsible appointment at a Maternity Hospital.

The salary is at the rate of £150 per annum, rising by annual increments of £25 to £200 per annum, together with the usual residential emoluments.

The appointment is for a period of one year, the first instance but may be renewed for a further period of one year.

Forms of application may be obtained from the County Medical Officer of Health, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded not later than Monday, October 10th, 1938.

GEORGE EHLERTON, Clerk of the County Council.
County Offices, Preston.
September 19th, 1938.

KENT COUNTY COUNCIL.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Resident Assistant Medical Officer at the County Hospital, Dartford (655 beds).

The salary for the appointment is £250 a year, with residential emoluments which are valued at £120 a year.

The appointment is a whole-time one and is determinable by three calendar months' notice on either side.

Forms of application can be obtained from the Public Assistance Officer, Tonbridge Road, Maidstone, to whom applications must be sent by stone, 10 a.m. on Monday, October 10th, 1938.

W. L. PLATTS, Clerk of the County Council.
Sessions House, Maidstone.
September 20th, 1938.

THE LEEDS VOLUNTARY HOSPITAL COUNCIL.

THE GENERAL INFIRMARY AT LEEDS (673 Beds.)

The Council invite applications for the post of HONORARY ASSISTANT SURGEON at the above Institution. Candidates must be fully qualified medical practitioners, and must be members of the Royal College of Surgeons in England.

Information relative to the post will be sent on reference to the Hon. Secy.

Twenty-five copies of application forms must be addressed to, and received by, the Hon. Secy. not later than October 10th, 1938.

Envelopes to be enclosed "Public Assistance Staff."

S. CLAYTON FRYER, Secretary.
The General Infirmary at Leeds.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE.

During 1938, the Secretary of State for the Colonies proposes to select a number of Medical Officers to fill vacancies, the majority of which will occur in Tropical Africa and Malaya.

QUALIFICATIONS.—Candidates must be British subjects of European parentage, under 35 years of age, and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

SALARY.—Initial salaries vary from £600 to £700, and rise by increments to a maximum of between £1,000 and £1,200.

PRIVATE PRACTICE.—Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions.

QUARTERS.—In Tropical Africa, free quarters, or an allowance in lieu, are provided. In Malaya, quarters are provided at an annual rental not exceeding 6% of the officer's salary.

PASSAGES.—Free first-class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages.

TERMS OF APPOINTMENT.—The appointments are pensionable, subject to a probationary period which varies from two to three years.

COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE.—Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas.

DUTIES.—Although Medical Officers are appointed in the first instance for general service, there are opportunities for work in special branches of medicine and surgery, in public health, and in medical research.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 8, Buckingham Gate, London, S.W. 1.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than November 21st, 1938.

METROPOLITAN BOROUGH OF GREENWICH.

JUNIOR ASSISTANT MATERNITY AND CHILD WELFARE MEDICAL OFFICER.

The Council of the Metropolitan Borough of Greenwich is prepared to receive applications from registered Medical Practitioners for the appointment of Junior Assistant Maternity and Child Welfare Medical Officer in the Borough of Greenwich. Applicants must have had experience in connection with Maternity and Child Welfare work generally, must be a registered Medical Practitioner who, prior to April 1st, 1930, had held the appointment of Medical Officer of an Ante-Natal Clinic with the approval of the Minister of Health, or who, subsequent to qualification, has had at least three years' experience in the practice of practical midwifery and special experience of possession of the Diploma in Public Health and Incident Obstetric experience will be considered additional qualification.

The person to be appointed will act generally under the direction and supervision of the Medical Officer of Health, who is the Administrative Medical Officer of the Maternity and Child Welfare Services. The salary will be at the rate of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum.

The successful candidate will be required to reside in the neighbourhood of the Borough Council's Maternity Home, to devote the whole of his or her time to the service of the Council, and not to engage in private practice.

The appointment will be subject to the provisions of the Council's Superannuation Acts, and will be terminable by three months' notice in writing on either side.

Applications must be made on forms to be obtained from the undersigned, stating age, qualifications, and experience, and accompanied by copies of not more than three recent testimonials, and must be sealed up and endorsed "Junior Assistant Maternity Medical Officer," and reach me not later than 12 o'clock noon on Wednesday, October 5th, 1938.

Canvassing members of the Council, either directly or indirectly, will be a disqualification. Stamped addressed foolscap envelope must accompany application for form.

Town Hall, D. J. REASON,
Greenwich, S.E.10. Town Clerk.
September 23rd, 1938.

LANCASHIRE COUNTY COUNCIL.

PUBLIC ASSISTANCE COMMITTEE.

LAKE HOSPITAL AND DARNTON HOUSE. Ashton-under-Lyne, near Manchester.

APPOINTMENT OF JUNIOR RESIDENT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners for the appointment of Junior Resident Medical Officer at the above Hospital and Institution, comprising 300 and 525 beds respectively. The Hospital is recognized as a complete Training School for Nurses.

Candidates must be unmarried. Salary at the rate of £225 per annum, together with the usual residential emoluments.

The appointment will, in the first instance, be for a period of six months, the successful applicant being eligible for reappointment for a further period of six months at the end of that period.

Forms of application may be obtained from the County Medical Officer of Health, Public Assistance (Hospital and Medical) Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded not later than Saturday, October 15th, 1938.

County Offices, GEORGE ETHERTON,
Preston. Clerk of the County Council.
September 26th, 1938.

ESSEX COUNTY COUNCIL.

JUNIOR RESIDENT MEDICAL OFFICERS.

The County Council of the Administrative County of Essex invite applications for the appointment of two Junior Resident Medical Officers at the Oldchurch County Hospital, Romford. Each appointment is for a period of one year, and the salary will be at the rate of £250 per annum, together with the usual indoor emoluments, value at £160 per annum. Experience in the Maternity Department of a hospital will be considered an additional qualification in respect of one of the appointments. The successful candidates will be required to pass a medical examination and will be subject to the Council's Sick Pay Rules and Regulations, a copy of which will be forwarded on application. Applications on the prescribed form, obtainable from the undersigned, should be addressed to me and delivered at the County Hall, Chelmsford, not later than 10 a.m. on Tuesday, October 11th, 1938.

County Hall, E. S. HOLCROFT,
Chelmsford. Clerk of the County Council.
September 20th, 1938.

MIDDLESEX COUNTY COUNCIL.

MIDDLESEX COUNTY COUNCIL MATERNITY HOSPITAL, Heathborne Road, Bushey Heath, Herts.

RESIDENT ASSISTANT MEDICAL OFFICER (woman) required—must be registered medical practitioner, preferably M.C.O.G. or D.C.O.G., with previous resident appointment in general hospital and special experience and knowledge of obstetrics.

Appointment for four years only (subject to medical examination), is held during pleasure of Council, and terminable by one month's notice on either side.

Salary £400-£25-£475 p.a. with board, lodgings and laundry valued at £100 p.a. Contributions to Superannuation Fund will be required from April 1st, 1939. Possibility of retention on established staff, with £500 p.a. max.

Whole-time duties, such as County Council may direct, under supervision of Medical Superintendent and Obstetric Surgeon of Redhill County Hospital, as an annex. Duties include medical charge of the 48 beds and attendance at ante-natal clinics at Redhill.

Written applications, with copies of not more than three recent testimonials, to be sent to undersigned in envelopes endorsed "Mat. Hosp.—A.M.O." by October 15th, 1938—disclosing relationship to any member or officer of Council. Canvassing, direct or indirect, disqualifies. C. W. RADCLIFFE, "Z,"
Gulldhall, Westminster, Clerk of the County Council.
S.W.1.

WEST RIDING OF YORKSHIRE MENTAL HOSPITALS BOARD.

APPOINTMENT OF AN ASSISTANT MEDICAL OFFICER.

WADSLEY MENTAL HOSPITAL.

Applications are invited for the appointment of an Assistant Medical Officer in the Board's service at the above Mental Hospital, at a commencing salary of £350 per annum, rising by annual increments of £25 to a maximum of £450, together with emoluments (board, apartments and laundry), valued at £120 per annum. The Board will allow an extra £50 per annum to the successful candidate who (whilst on this scale) holds or obtains the Diploma in Psychological Medicine, for which this Hospital affords special study facilities.

It will be an advantage if candidates have had at least one year's experience in general medicine after qualification.

The appointment is subject to the provisions of the Asylums Officers' Superannuation Act, 1909, Class 1.

Applications, with copies of not more than two recent testimonials, stating age and full particulars, to reach the Medical Superintendent, West Riding Mental Hospital, Wadsley, Sheffield, 6, not later than October 10th, 1938.

There is no printed form of application. Board Offices, G. L. BANNER,
Wakefield. Clerk of the Board.
September, 1938.

THE MIDDLESEX HOSPITAL, W.I.

Applications are invited from qualified medical men holding the D.A., or who intend shortly to do so.

Duties will include ANAESTHETICS and a RESIDENT ANAESTHETIC research in anaesthetics. The first place will be resident. Salary £300 per annum less the value of board and residence provided.

Further particulars may be obtained from the undersigned, to whom applications, supported by copies of testimonials, must be sent by Saturday, October 15th, 1938.

S. R. C. PLIMSOLL,
Secretary-Superintendent.

THE WEIR HOSPITAL. Weir Road, Balham, S.W.12. (30 Beds.)

SENIOR RESIDENT MEDICAL OFFICER (male, unmarried) required the middle of October. Salary £250 per annum, with board, residence, and laundry. Candidates must be fully qualified and duly registered.

Applications, with copies of three testimonials, to be sent to the Secretary, from whom further information may be obtained.

THE INFANTS HOSPITAL. Viney Square, Westminster, S.W.1.

Applications are invited for the post of HONORARY ANAESTHETIST to attend on Monday afternoons. An honorarium of £25 per annum will be paid in respect of the appointment. Particulars of the appointment, and information as to the submission of testimonials, etc., may be obtained from the undersigned, to whom applications must be delivered not later than October 25th 1938. ARNOLD TUNSTALL, Secretary.

COUNTY BOROUGH OF ROTTERHAM.

TUBERCULOSIS OFFICER; MEDICAL SUPERINTENDENT, OAKWOOD HALL SANATORIUM; AND MEDICAL SUPERINTENDENT, ISOLATION HOSPITAL.

Applications are invited from fully qualified medical practitioners under the age of 45 years for the above post, at a commencing salary of £750 per annum, rising by three biennial increments of £50 and one of £37 10s. to £937 10s., less the emolument of a house to the value of £52. The successful applicant will be required to reside at the Oakwood Hall Sanatorium, where an Assistant Medical Officer is also resident.

Applicants must possess the D.P.H. and must have had practical experience of all forms of tuberculosis, the administration of a sanatorium, in dispensary work, and the training of nurses for examination. The selected candidate will also be in charge of the Isolation Hospital, and experience in infectious diseases is essential. He will be required to work under the direction of the Medical Officer of Health and to devote the whole of his time to the duties of the office and to undertake such other work as may be assigned from time to time.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination at to physical fitness.

The appointment will be terminable by three months' notice on either side.

Applications, stating age, experience, and qualifications, accompanied by copies of not more than three recent testimonials and endorsed "Tuberculosis Officer," should be received by the undersigned not later than Wednesday, October 12th, 1938.

Forms of application may be obtained from the Medical Officer of Health, Municipal Offices, Rotherham.

CHAS. L. DEES FORGES,
Municipal Offices, Rotherham. Town Clerk

COUNTY BOROUGH OF ROTTERHAM.

MEDICAL SERVICES COMMITTEE.

ASSISTANT RESIDENT MEDICAL OFFICER

The Medical Services Committee invite applications for the position of Assistant Resident Medical Officer at their Alina Road Hospital, Rotherham, for a period of twelve months. Preference will be given to those candidates who have held a resident appointment in a General Hospital, or a Municipal Hospital, for a period of at least six months.

The Hospital has approximately 350 Acute Beds and 50 Chronic Beds. There is an associated district service with Out-Patient Department. There are four Assistant Resident Medical Officers, and one Deputy Medical Superintendent and Obstetric Officer. The work that will be required of this medical officer will be chiefly medical, and there will be district visiting. The salary is £450 per annum, together with the usual residential emoluments.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act. The successful candidate will be required to pass a medical examination. The person appointed will be required to act under the general direction of the Medical Superintendent, and in any sphere which the Council may from time to time direct.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, Rotherham, and must be returned to the undersigned, and to "Assistant Resident Medical Officer, Alina Road Hospital," not later than noon on Wednesday, October 12th, 1938.

Municipal Offices, CHAS. L. DEES FORGES,
Rotherham. Town Clerk

APPOINTMENTS.—Contd.

WEST LONDON HOSPITAL, HAMMER-SMITH, W.6. (239 Beds.)

There is a vacancy for the newly created post of **HONORARY PHYSICIAN FOR PSYCHOLOGICAL MEDICINE**. Candidates, who may be men or women, should be Members or Fellows of the Royal College of Physicians, London, and should have had some experience in Child Psychiatry. A Diploma in Psychological Medicine is desirable. The candidate appointed would be expected to undertake at least one Out-Patient Session per week and such teaching as may be required by the Medical School. The appointment does not carry with it the charge of any Hospital beds.

Applications, accompanied by copies of testimonials, must reach me by first post on Thursday, October 20th. Candidates must attend a meeting of the Medical Council at 4.30 p.m. on Friday, October 21st, and prior to that date call upon and send copies of their application and testimonials to each member thereof. They must not canvass members of the Board, but, nevertheless, must send copies of their application and testimonials to each member thereof and, if so notified, be in attendance at a meeting of the Board at 5 p.m. on Tuesday, October 25th, when the appointment will be made.

H. A. MADGE, Secretary.

WEST LONDON HOSPITAL, HAMMER-SMITH, W.6. (239 Beds.)

An additional **HONORARY REGISTRAR** is required for the Throat, Nose, and Ear Department. The appointment is for one year from November 1st next and, subject to annual re-election, may be extended for a period of not longer than three years.

Applicants must be duly qualified registered Medical Practitioners with previous experience in oto-laryngology.

Applications, accompanied by copies of testimonials, must reach me not later than Thursday, October 20th, first post. Candidates must attend a meeting of the Medical Council at 4.30 p.m. on Friday, October 21st, and, prior to that date, call upon and send copies of their applications and testimonials to each member thereof. They must not canvass members of the Board but, nevertheless, must send copies of their application and testimonials to each member thereof and, if so notified, be in attendance at a meeting of the Board at 5 p.m. on Tuesday, October 25th, when the appointment will be made.

H. A. MADGE, Secretary.

WEST LONDON HOSPITAL, HAMMER-SMITH, W.6. (239 Beds.)

CHIEF ASSISTANT to the Department for **TREATMENT OF INJURIES** required. The post is a resident one and the duties commence on November 1st. Salary at the rate of £200 a year, with board and lodging. Candidates must be duly qualified registered Medical Practitioners, and it is desirable that they should possess one of the higher Surgical Degrees or Diplomas. They must have had special experience in the treatment of fractures. The appointment, which is terminable by a month's notice on either side, will be for a period of six months in the first instance, but this period may be extended.

Applications, which must be made on printed forms obtained from me, must reach me not later than first post on Thursday, October 20th. Candidates will be required to call upon such members of the Medical Staff as directed, to be in attendance at a Medical Council Meeting at 4.30 p.m. on Friday, October 21st, and the House Committee Meeting at 5 p.m. the same day, when the appointment will be made.

H. A. MADGE, Secretary.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners of at least one year's standing to undermentioned positions. Candidates must have held resident appointment in a general hospital for at least six months. Married quarters not available.

ASSISTANT MEDICAL OFFICERS (Grade II).—Salary £250 a year, together with board, lodging and washing. Appointment for one year only in first instance (renewable for a second year under certain conditions).

(a) **DULWICH HOSPITAL**, East Dulwich Grove, S.E.22 (two positions):

(1) Duties mainly medical, obstetrical experience desirable.

(2) Duties mainly medical, experience in anaesthetics desirable.

(b) **QUEEN MARY'S HOSPITAL**, Sidcup, Kent.—Duties mainly medical (male convalescent hospital), surgical experience desirable.

(c) **ST. JAMES' HOSPITAL**, Ouseley Road, Balham, S.W.12.—Duties obstetrical, gynaecological and anaesthetic experience essential.

(d) **ST. MARY ISLINGTON HOSPITAL**, Highgate Hill, N.19.—Duties mainly medical.

(e) **ST. MATTHEW'S HOSPITAL**, Shepherdess Walk, N.W.1.—Medical duties.

*No accommodation for a woman.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division, 2a), County Hall, S.E.1, returnable by October 17th.

Canvassing disqualifies.

COUNTY BOROUGH OF SOUTHEND-ON-SEA.

SOUTHEND MUNICIPAL HOSPITAL.

The House Committee of the Town Council invite application for the appointment of Resident Deputy Medical Superintendent at their Municipal Hospital situated at Rochford, Essex (460 Beds). Extensions to existing hospital buildings are now in course of erection. There is a staff of visiting Consultants, and the hospital is a recognized training school.

The applicants must have had experience in emergency surgery and treatment of fractures, and previous administrative experience will be a recommendation.

Salary £200 per annum, rising by annual increments of £25 to £600 per annum, together with board, residence and treatment of Enrolments valued at £150 per annum for Superannuation purposes.

The appointment is a designated post under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Application forms to be obtained from the Medical Officer of Health, The Municipal Health Centre, Warrior Square, Southend-on-Sea, and should be returned to him on or before October 19th, 1938.

Town Clerk's Office, H. I. WORWOOD, Southend-on-Sea. Town Clerk.

THE QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2. (204 Beds.)

The Board of Management invite applications for the post of **EAR, NOSE AND THROAT SURGEON**. Candidates must be Fellows of the Royal College of Surgeons of England or of another recognized College. Attendance required, two half-days weekly. The appointed candidate will have charge of beds.

An honorarium to cover travelling expenses will be paid. Further information may be obtained from the undersigned, to whom applications, with copies of three recent testimonials, should be sent not later than October 12th, 1938.

CHARLES H. BESSELL, Secretary.

BIRMINGHAM AND MIDLAND EYE HOSPITAL. (114 Beds.)

Applications are invited from duly qualified Medical Practitioners for the post of **HOUSE SURGEON** at the above Hospital.

Salary £130 per annum (rising to £150 at the end of six months satisfactory service) and £10 laundry allowance.

The Resident Staff consists of a Resident Surgical Officer and three House Surgeons.

Applications, with testimonials and evidence of registration, should be forwarded immediately to the undersigned.

J. W. PEARCE, House Governor.
Church Street, Birmingham, 3.

ST. ALBANS AND MID-HERTS HOSPITAL, Church Crescent, St. Albans.

(50 Beds.) (One Resident Medical Officer.)

Applications are invited for the post of **RESIDENT MEDICAL OFFICER**. Salary £150 per annum, with board, residence, and laundry.

The post will become vacant on October 17th next.

Applications to be sent to the Secretary, St. Albans and Mid-Herts Hospital, Church Crescent, St. Albans. Telephone No. 4516.

ST. BARTHOLOMEW'S HOSPITAL, Rochester. (200 Beds.) (Four Residents.)

The House and Finance Committee invite applications for the posts of **HOUSE PHYSICIAN** and **HOUSE SURGEON**, which will become vacant on October 25th, 1938.

Candidates must be unmarried, qualified, and registered medical men. The appointment is for six months. Salary at the rate of £150 per annum, with board, residence, and laundry.

Applications, stating age, qualifications, experience, etc., accompanied by copies of two testimonials or one from the Dean of the candidate's Medical School should be received by the Superintendent-Secretary not later than noon, October 13th, 1938.

Canvassing the Honorary Staff will disqualify.

TILBURY HOSPITAL, ESSEX (Seamen's Hospital Society). (92 Beds.)

HOUSE SURGEON (male) required for six months as from October 1st. Salary £140 per annum, with board, residence, and laundry.

Applications, with copies of three testimonials, to be sent immediately to the undersigned.

F. A. LYON, Secretary.
Seamen's Hospital Society,
Greenwich, S.E.10.

THE BIRMINGHAM UNITED HOSPITAL (Medical School.)

Applications are invited for the post of **ASSISTANT BACTERIOLOGIST**.

Candidates must be Registered Medical Practitioners. Commencing salary £350 per annum.

Applications must be sent to the undersigned (from whom all further particulars can be obtained), stating age, experience, qualifications and nationality, with copies of recent testimonials, not later than Monday, October 24th.

The Genie Hospital, G. HURFORD, Secretary.
Edgbaston, Birmingham, 15.

LONDON HOSPITAL, E.1.

There is a vacancy for the post of **CLINICAL ASSISTANT** in the X-Ray Department. Candidates must be fully qualified medically. Experience in Radiology is essential. The Honorarium of the post is £100 per annum.

Applications, with testimonials, should be sent to the House Governor, and should arrive not later than Saturday, October 22nd.

ARTHUR G. ELLIOTT, House Governor.

"LACTOGEN"

as easy to Assimilate as Natural Milk

The special Lactogen process ensures a product so closely akin to the characteristics of natural milk that not only are the proportions of its food elements practically identical, but the physiological character is also similar in every important factor. The fat globules, through homogenisation, are even smaller than those of breast milk, whilst the curd is just as light and flaky as that of the natural milk. For these reasons Lactogen is as readily digestible and as assimilable as Baby's natural diet—and the food you are safe in recommending in cases where breast feeding is inadequate or impossible.

THE BETTER MILK FOR BABIES

FREE SAMPLES with detailed literature will be sent to any mother on request to the Medical Products Division, Nestlé's Milk Products Ltd., 1, St. George's House, 6 & 7, London, E.C.3.

The Prophylaxis of Diphtheria

The following prophylactics are made and
standardised at

THE EVANS BIOLOGICAL INSTITUTE

A.P.T. Evans

(Alum Precipitated Toxoid)

A "two-dose" prophylactic prepared by precipitating the antigenic fraction of formal toxoid of high value with alum. The first injection should be 0.1 to 0.2 cc. and the final injection 0.5 cc. after two weeks. For children of eight years and under.

T.A.F. Evans

(Toxoid Antitoxin Floccules)

T.A.F. should be used when the subject is more than eight years of age. T.A.F. has a high immunizing efficiency whilst reaction is rare.

T.A.M. Evans

(Toxoid Antitoxin Mixture)

Produces immunity more slowly and is generally recognised to be less efficient than A.P.T. and T.A.F.

F.T. Evans

(Formal Toxoid)

An efficient prophylactic. It may cause disturbance in some older children and in adults. It is recommended that its use be restricted to children between 1 and 8 years of age.

Dosage of F.T., T.A.M., and T.A.F.

These "three-dose" prophylactics are administered subcutaneously. With the F.T. and T.A.M. the doses are 0.5 cc., 1 cc. and 1 cc., but with T.A.F. each 1 cc. A course of 0.5 cc., 1 cc. and 1.5 cc. has also been suggested. It is recommended that the intervals between the injections should be one or preferably two weeks.

In the very few instances where a positive Schick reaction is obtained after such a course of treatment further injections are necessary to establish immunity. It is recommended that the Schick Test be made not earlier than eight weeks after the third injection.

*(Special prices and detailed literature will be forwarded to
Public Health Authorities)*

J. & A. CHURCHILL

LTD

THREE NEW BOOKS

A TEXTBOOK OF BIOCHEMISTRY

By A. T. CAMERON, D.Sc.,
F.I.C., F.R.S.(C)

Professor of Biochemistry, Faculty of
Medicine, University of Manitoba.

New (5th) Edition. 3 Plates and 25
Text-figures. 15s.

This edition has been almost completely rewritten, and large sections have been rearranged. Includes several new illustrations.

BIOCHEMISTRY FOR MEDICAL STUDENTS

By W. V. THORPE, M.A., Ph.D.

Reader in Chemical Physiology,
University of Birmingham.

4 Plates and 33 Text-figures. 12s. 6d.
(Just Published.)

This volume is an endeavour to supply the student of medicine or dentistry with those biochemical facts that he will require especially.

ELEMENTARY ANATOMY AND PHYSIOLOGY

By JAMES WHILLIS, M.D.,
M.S., F.R.C.S.

University Reader in Anatomy, Guy's
Hospital Medical School.

87 Illustrations. 12s. 6d.

(Just Published.)

Correlates structure and function, and emphasises the essential inter-dependence of Anatomy and Physiology.

THREE STANDARD BOOKS

DISEASES OF THE EYE

By SIR JOHN HERBERT
PARSONS, C.B.E., D.Sc.,
F.R.C.S., F.R.S.

Consulting Ophthalmic Surgeon,
University College Hospital, London.

New (9th) Edition. 21 Plates, 29 in
Colour. 360 Text-figures. 18s.

This favourite book gives details of
new drugs and new methods of treatment.

THE OPERATIONS OF SURGERY

8th Edition.

By R. P. ROWLANDS, M.S.,
F.R.C.S., PHILIP TURNER,
M.S., F.R.C.S., and Collaborators.

Vol. I. 435 Illustrations, 38 in Colour, 36s.

Vol. II. 514 Illustrations, 4 in Colour, 36s.

"The book remains one of the best
guides to operative surgery in the
English language."

—THE BRITISH JOURNAL OF SURGERY.

THE RADIOLOGY OF BONES AND JOINTS

By JAMES F. BRAILSFORD,
M.D., M.R.C.S.

Radiological Demonstrator in Living
Anatomy, University of Birmingham.

Second Edition. 349 Illustrations. 30s.

"This book is long likely to remain
the standard international work on the
radiology of bone diseases."

—BRITISH JOURNAL OF RADIOLOGY.

THREE MODERN BOOKS

A SHORT TEXTBOOK OF MIDWIFERY

By G. F. GIBBERD, M.S.,
F.R.C.S., M.C.O.G.

Assistant Obstetric Surgeon,
Guy's Hospital.

187 Illustrations. 15s.

"The author and publishers deserve
the greatest possible praise for this work,
which is of a practical character, illus-
trated by excellent photomicrographs
and line drawings . . . is undoubtedly
one of the best books available on the
subject of modern midwifery."

—THE PRACTITIONER.

A SHORT TEXTBOOK OF SURGERY

By C. F. W. ILLINGWORTH,
M.D., F.R.C.S.(Ed).

Lecturer in Clinical Surgery,
University of Edinburgh.

8 Plates and 179 Text figures. 21s.

"It covers the whole field of surgery
and should prove invaluable to the
student as the important and common
surgical conditions are dealt with 'in
extenso' . . . will take its place as one
of the really valuable books which
students require."

—THE MEDICAL PRESS.

THE ESSENTIALS OF MATERIA MEDICA, PHARMACOLOGY AND THERAPEUTICS

By R. H. MICKS, M.D.,
F.R.C.P.I.

Professor of Pharmacology,
Royal College of Surgeons in Ireland.

New (2nd) Edition. 12s. 6d.

"As a concise account of the essentials
of modern therapeutics it deserves wide
popularity among students and practi-
tioners of medicine."

—BRITISH MEDICAL JOURNAL.

THREE VALUABLE BOOKS

EDEN AND LOCKYER'S GYNÆCOLOGY

4th Edition. Revised by SIR H.
BECKWITH WHITEHOUSE,
M.B., M.S., F.R.C.S., F.C.O.G.

Professor of Midwifery and Diseases
of Women, University of Birmingham.

36 Coloured Plates and 619 Text-figures.
38s.

"One of the best standard medical
textbooks ever produced in this country."

—THE LANCET.

ANTENATAL AND POSTNATAL CARE

By F. J. BROWNE, M.D.,
F.R.C.S.(Ed), F.C.O.G.

Professor of Obstetrics and Gynaecology,
University of London.

Second Edition. 79 Illustrations. 18s.

"It would be difficult to improve upon
this book, since it covers the ground of
its title so well and thoroughly . . . can
be commended to every class of reader."

—THE MEDICAL PRESS.

MODERN PSYCHOLOGY IN PRACTICE

By
W. LINDESAY NEUSTATTER,
M.B., M.R.C.P.

Clinical Research Assistant, Department
of Psychological Medicine,
Guy's Hospital.

10s. 6d.

"This is a thoroughly practical text-
book on the elementary aspects of
applied psychology, and the author's
obvious wide experience, together with
his sincerity, make it a book which can
be of use to all practi-

—THE PRACTITIONER.

WHAT'S GOING UP YOUR CHIMNEY?

For rooms where you want warmth quickly for short periods, a gas fire! Choice of many colours. Quick, clean heat. They ventilate a room automatically.

**NO
SMUTS
NO
SMOKE
with**

The open coke fire burns without dirt or smoke. Saves 2d. in the 1/- on your fuel bills. Gas-ignited on tap. Very convenient, very modern.

Issued by THE BRITISH COMMERCIAL GAS ASSOCIATION, GAS INDUSTRY HOUSE, 1, GROSVENOR PLACE, LONDON, S.W.1.

BAILLIÈRE, TINDALL AND COX

Wakeley and Orley

TEXTBOOK OF
NEURO-RADIOLOGY

By CECIL P. G. WAKELEY,
D.Sc., F.R.C.S. and
ALEXANDER ORLEY, M.D.,
D.M.R.E.

Pp. xiv+336. 229 Illustrations.
Price 25s. Postage 7d. Abroad
15s. 4d.

"Mr. Wakeley and Dr. Orley have done their work well, and this book should prove most useful to all neurologists and radiologists. The descriptions of the different radiological techniques are excellent and the illustrations generally are of a high standard."—*Practitioner*.

Nicholls

ARMY MEDICAL
SERVICES IN WAR

By Lieut.-Col. T. B. NICHOLLS,
M.B., Ch.B., R.A.M.C.

Pp. xiv+372. Price 10s. 6d.
Postage 6d. Abroad 15s. 1d.

"An encyclopaedia of knowledge and information concerning the medical services in war. . . . Lieut.-Colonel Nicholls presents us with a mass of information on almost every aspect of the subject."—*British Medical Journal*.

Minnitt

GAS AND AIR
ANALGESIA

By R. J. MINNITT.

Pp. viii+84. With 12 plates.
Price 3s. Postage 4d.

An excellent introduction for Gas and Air Analgesia for the general practitioner, the anaesthetist and the midwife. The apparatus used and the technique of administration are fully described, while contra-indications to use of this method are also dealt with.

Nicholls

TROPICAL
NUTRITION AND
DIETETICS.

By LUCIUS NICHOLLS,
M.D., B.C.

Pp. xi+164 with 9 figures.
Price 7s. 6d. Postage 6d.
Abroad 8d.

"A clear, concise and practical account. It is meant primarily for medical practitioners who work among the masses in these regions, but those working elsewhere will find it worth their while."—*British Medical Journal*.

Jones

PAPERS ON PSYCHO-
ANALYSIS

Fourth Edition.

By ERNEST JONES, M.D.,
M.R.C.P.

Pp. x+643. Price 25s. Postage
7d. Abroad 15s. 3d.

"His language is always clear and the book can be recommended not only to the specialist, but to the medical man who wants an authoritative exposition of psycho-analytical teaching."—*Lancet*.

Lake

THE FOOT

Second Edition.

By NORMAN LAKE, M.D.,
M.S., D.Sc., F.R.C.S.

Pp. viii+366. 113 Illustrations.
Price 12s. 6d. Postage 6d.
Abroad 15s.

"All the common and everyday affections receive great attention, and that is why it will be of inestimable value to the student and practitioner alike. . . . The illustrations are excellent. An admirable monograph."—*Medical Press and Circular*.

Feldman

CLINICAL
RÖNTGENOLOGY OF
THE DIGESTIVE
TRACT

By MAURICE FELDMAN,
M.D.

Pp. 1,010. 359 Tables. 179
Illustrations. Price 45s. Post-
age 8d. Abroad 25s.

A book that gives every possible item of information, a textbook for the general practitioner and for the physician, to enable them to check and support accurately every diagnosis of diseases of the gastro-intestinal tract.

For further particulars apply to

7 and 8, Henrietta Street, Covent Garden, London, W.C. 2.

LEWIS'S BOOKS

Chapter 2 from BACK TO ACTIVITY*

Important steps in the fitting of ARTIFICIAL LIMBS

Measuring the length of the shin. One of 31 essential measurements and checks recorded and filed for the fitting of a Desoutter Artificial Limb.

Taking the profile drawing of the amputation. Desoutter considers five such outlines are necessary in every case.

The amputation stump is covered with stockinette. Bony prominences and sensitive areas are marked with a copying pencil.

A plaster of Paris bandage is quickly applied up to a point 7 or 8 inches above the knee. When the plaster is set, the jacket retains an exact impression of the stump.

* The technique of stump preparation and limb-fitting is one of the subjects discussed very fully in "BACK TO ACTIVITY," by E. R. Desoutter. Other sections of the book survey very completely to what extent Desoutter Artificial Limbs can restore business, social and recreational activity to those who have undergone amputation. A copy will be sent on request.

BRANCHES IN ALL PRINCIPAL TOWNS.

PERSISTENT ERUPTIONS QUICKLY RELIEVED *

Because it contains a perfectly natural antiseptic—distillates of peat—Sphagnol Ointment has a rapid and beneficial effect on the eruption. It has a twofold action. From the first dressing it soothes irritation and burning sensations. Then, as its antiseptic peat distillates penetrate, the local treatment effectively assists in general measures to clear away the toxic matter which is the source of the trouble. We have on record many cases in

which a decided improvement has been shown after only three days, and where, before a week had elapsed, marked benefit had resulted.

In case you have had no personal experience of Sphagnol, we shall be pleased to send you a clinical size sample for testing if you will write to Peat Products (Sphagnol) Ltd., Dept. B.M.J.15, 21, Bush Lane, London, E.C.4.

KOROMEX METHOD

The Koromex Occlusive Diaphragm is made in a range of sizes to fit each individual patient; pure latex rubber pessaries. Light and comfortable; practically unfelt. Two-year durability guaranteed. Practitioners and birth control clinics, for more certain protection, prefer to use the perfect fitting Koromex Diaphragm with

KOROMEX VAGINAL JELLY

Stainless and prolonged effective—permeable. The carefully gauged viscosity of Koromex Jelly affords the all-important mechanical block. No toxicity or irritation . . . makes the diaphragms easier to insert.

Advise the Koromex Method. Your patient will be grateful.

A sample of Koromex Jelly will be sent on application to medical practitioners; also a booklet, the Physician's Guide, on the technique of fitting the Occlusive Koromex Diaphragm. No charge. Write to

The Highest Record of PROVEN SUCCESS in Contraceptives

- Evidence of the high degree of efficacy of the Koromex Method is based upon the experience of 234 clinics—140 hospitals—over 50,000 physicians.

THE KOROMEX METHOD

KOROMEX DIAPHRAGM + KOROMEX JELLY

- The Koromex Diaphragm appears on the National Birth Control Association's approved list with seven Prentif products, including Condoms, Sheaths, Jellies and Suppositories. Illustrated descriptive Price List on request.

NO WAITING—NO RISK—NO RESPONSIBILITY!

This desirable combination of circumstances in intravenous therapy is now possible with Baxter's Intravenous Solutions in the "Vacoliter" Container.

They are instantly available and have proved themselves to be absolutely sterile, stable, and unquestionably safe.

It is this history of safety over many years of experience that enables Baxter Laboratories to accept the full responsibility.

We welcome an opportunity to demonstrate a complete and economical intravenous service to you at any time.

B.D.H. COMMON COLD VACCINES

The common cold is regarded as being due primarily to infection by a virus, with secondary invasion by the organisms usually found in the upper respiratory tract. It is believed that these organisms which are normal inhabitants of the naso-pharynx may, under certain conditions, assume a pathological rôle.

No vaccine against the infecting virus is at present available, and the value of the Common Cold Vaccines lies in their power to diminish the activity of the secondary invaders. Three vaccines against these invaders are prepared in the B.D.H. laboratories :

B.D.H. Common Cold Vaccine (Anticatarhal)

B.D.H. Influenza Vaccine (Mixed)

B.D.H. Influenza Vaccine (British Army Formula)

DOSAGE: The vaccines are generally used for prophylaxis, a course of four injections being given: 0.25 c.c., 0.5 c.c., 1.0 c.c., 1.0 c.c. at weekly intervals; they may be given, also, therapeutically—small doses being employed.

PALATABLE IRON

Ovoferrin Brand Colloidal Iron Tonic, iron in its most minute colloidal subdivision, is palatable, odourless, pleasant to take. It is ideal in pregnancy and in pediatrics. It will not stain the teeth, constipate or irritate the gastro-intestinal tract. We believe it to be the only hematinic simple enough, assimilable enough, agreeable enough for long term iron feeding. The adult dose is one tablespoonful in milk or water after meals and at bedtime. Prescribed in 11-ounce bottles. Write for free professional sample.

Testimony by members of the Medical Profession . . .

Read what a doctor says:—

"I feel I can with confidence advise my patients to use 'Ty-phoo' tea even when complaining that other kinds procure gastric irritation. I have never known its use to be followed by dyspeptic disturbances."

M.D.

The above is one of many hundreds of testimonials received.

Medical men and women, throughout the country, are recommending our pure "Ty-phoo" tea as indicated by the daily despatch of hundreds of samples which doctors direct us to send to their patients.

Delicious

Ty-phoo

TEA

is so mild that it does not cause indigestion.

Further,

you save by using "Ty-phoo," for being so rich in "leaf-edge" it "goes just half as far again" as coarse astringent tea.

Write to

Sumner's Ty-phoo Tea Ltd., Birmingham, 5, for a FREE sample.

(This offer applies only to the British Isles. We regret that we cannot send "Ty-phoo" tea abroad.)

COMMON COLD

AND

ANTI-CATARRH VACCINE (EVANS)

(LOCAL STRAINS)

For Prophylaxis and Treatment

The facilities of the pathological laboratories at **THE EVANS BIOLOGICAL INSTITUTE** enable us to issue vaccines prepared from organisms collected in the locality in which the vaccine is to be used. It will be appreciated that such vaccines are highly specific, producing a greater proportion of successful results than is usual with ordinary Stock Vaccines.

The formulæ have been evolved, after many years' experience, as having a comprehensive selection of organisms as found in numbers of typical cases, in the correct proportions.

EVANS' COMMON COLD AND ANTI-CATARRH VACCINES (Local Strains) are issued as follows:

| | | |
|--|-----------------|--|
| Boxes of 3 x 1 cc. Ampoules, No. 3 Vaccine (Prophylaxis) | .. 7/- per box | Also in 5 cc., 10 cc. and 25 cc. bottles |
| Boxes of 6 x 1 cc. Ampoules, No. 1 Vaccine (Treatment) | .. 14/- per box | and in single Ampoules |

MANDECAL

(Compound Calcium Mandelate B.D.H.)

*In the treatment
of urinary infections*

The superiority of Mandecal over other mandelic acid preparations prescribed in the treatment of urinary infections lies in the fact that, whilst it is equally effective, therapeutically, its administration causes less irritation to the gastric mucosa and eliminates the nausea so frequently associated with this form of therapy.

Furthermore, Mandecal is simple of administration; being miscible with water, it is readily taken in a draught.

OVALTINE

IN PREGNANCY

THE physiological drain of calcium, phosphorus, vitamins and other important food elements calls for replacement during pregnancy. Composed of milk, eggs and malt, 'Ovaltine' supplies these essentials in a delightful form which does not overtax the unstable maternal digestion. A cup of 'Ovaltine' on arising, during the early months, is often effective in controlling sickness and has a food value greater than three eggs.

IN LACTATION

To maintain lactation to the eighth month is an ideal not often realized under modern conditions of life. Ample evidence is available to show that 'Ovaltine' has a definite action in increasing the flow and enriching the quality of the milk. It has, moreover, a beneficial effect on the health of mother and child. The flavour is so agreeable that it can be taken for prolonged periods without any distaste arising.

Bowel Treatment of Surgical Cases

THE use of purgative agents before operation is now disfavoured by many surgeons who prefer the patient to have a short preparatory course of "lubrication therapy." "Cristolax" is advocated for its lubricant and gentle laxative effect as well as its digestive and nutritive value. Clinical experience has definitely proved its worth.

For the regulation of the bowels after operation. "Cristolax" offers many advantages. Its bland, soothing, yet efficient action diminishes peristalsis and does not irritate the line of suture nor give rise to meteorism as many cathartics are liable to do.

"Cristolax" is medicinal paraffin of the highest purity and correct viscosity, so skilfully combined with "Wander" Dry Malt Extract that all unpleasant oiliness is entirely eliminated. Its routine use during convalescence restores normal bowel action.

HOW WHOLE WHEAT CRISPBREAD BENEFITS HEALTH

WHEAT has always been Man's first choice among the cereals, whenever climatic conditions did not prevent his getting it. That remains true of all bread, either white or wholemeal, either soft or biscuit-crisp. And Vita-Weat, the wheaten crispbread with the WHOLE of the wheat left in it, has advantages which entitle it to a very high place among the staple foods of the world.

Its Calorific Value

Bread is the 'energy component' and Vita-Weat, since it contains only 3 per cent. of water, has a fuel-value nearly twice that of ordinary bread—according to the *Practitioner* its caloric value is 2,132 per lb.

Each section of such a crispbread,—each 'slice,' so to speak—has a caloric value of 37. That is to say, that in meeting what is probably the greatest requirement of a national staple food Vita-Weat is almost twice as effective as the softer kinds of wheaten bread.

Starch and Digestion

A crispbread, obviously, calls for a more thorough chewing than a soft 'crumb' bread and salivation is therefore more healthily promoted. The starches and cellulose in Vita-Weat are also 'converted' into a more digestible form by the special processes which go to make a good crispbread—just as toast and crust have become greatly more digestible than bread in its quite 'unconverted' starchy form. While all the wheat-berry is used the bran and fibre are thoroughly disintegrated.

The result is, therefore, that the weight which quantities of 'unconverted' starch places on the digestion is almost entirely eliminated where Vita-Weat has been prescribed.

VITA-WEAT AND ITS ADVANTAGES

In addition to these great advantages of superior fuel-value and digestibility Vita-Weat retains the 'protective' elements of the wheat-berry which are frequently rejected in the 'refining' of white flours. Proteins, vitamins and minerals in which bread is normally deficient are present and the 'balance' of this crispbread as a food is therefore increased. The use of Vita-Weat can be shown to be especially desirable in cases of mild anaemia, liability to infection, lack of appetite, poor digestion, diabetes, obesity and as a food of 'protective' value to the teeth.

A little booklet has been prepared for the medical profession briefly summarising the medical case for a whole wheat crispbread and it will gladly be sent post free to any doctor on application to Peek Freon & Co. Ltd., Kestons Road, London, S.E.16

Paranasal Sinusitis

Fig. 1.—A sagittal section of a normal skull.

Fig. 2.—Complete exposure of the intricate cellular inter-communications and correlations of the frontal, sphenoidal, and maxillary sinus relations.

Fig. 3.—A semi-diagrammatic composite of Figs. 1 and 2.

'BENZEDRINE' BRAND INHALER

In a series of 306 cases showing varying degrees of paranasal sinusitis, treatment with 'Benzedrine' Brand Inhaler proved extremely helpful. Because of the great difficulty of approach to the complicated sinus structures, a volatile vasoconstrictor is of particular advantage in this condition. The illustrations show the anatomic difficulty of reaching these remote areas adequately by instrumentation or ordinary vasoconstrictors.

'Benzedrine' Brand Inhaler, used in the early stages of a nasal infection, frequently helps to abort or shorten conditions that would otherwise proceed to more serious complications.

(*Clin. Med. & Surg.*, Jan., 1937.)

In acute nasal sinusitis of childhood, where "the main object of treatment is to shrink the inside of the nose till the discharge comes away... a benzedrine inhaler is effective, and children like it." (*Brit. Med. Jour.*, April 30, 1938, p. 936.)

The Typical Arthritic

The commonest type of arthritic that the physician is called upon to treat is not, as a rule, seriously incapacitated. There is often considerable discomfort, but the joint involvement is slight, and the patient usually cannot be induced to undergo an expensive course of hospital treatment.

In this class of case—no less than in severe, chronic cases—'Calsiod' (calcium orthoiodoxybenzoate) provides a safe and effective form of treatment. It also has a wide field of usefulness in those ill-defined conditions loosely grouped under such terms as 'rheumatism,' 'lumbago,' 'neuritis,' 'fibrositis,' etc.

ABBOTT'S HALIVER MALT

with Viosterol

*Vitamins A, B₁, B₂ and D
Calcium and Phosphorus
Liver and Malt Extracts*

IN ONE PALATABLE PRODUCT

ABBOTT'S HALIVER MALT with Viosterol is biologically standardised for vitamins A, B₁, B₂ and D. Each teaspoonful is equivalent in vitamin A potency to at least one teaspoonful of high grade cod-liver oil; in vitamin D potency to five drops of Viosterol in Oil. In vitamins B₁ and B₂, three teaspoonfuls are equivalent to at least one cake of moist, compressed yeast. The liver extract in this preparation is a standardised extract and contains the necessary factors for the production of mature red blood corpuscles. The pure barley malt extract supplies diastase and a number of valuable nutritive substances. ● Each fluid ounce of Haliver Malt with Viosterol contains not less than: 27,000 International units of vitamin A; 50 International units of vitamin B₁; 50 Sherman units of vitamin B₂; 7,000 International units of vitamin D; the equivalent of 5 grs. of mono-calcium phosphate; and the equivalent of ½ oz. of fresh, mammalian liver. ● Because the vitamin A and D content of this product is supplied by Haliver Oil (halibut-liver oil, Abbott) and Viosterol, Haliver Malt with Viosterol is entirely free from the disagreeable "fishy" taste to which so many patients object in malt preparations containing cod-liver oil. ● Abbott's Haliver Malt with Viosterol is supplied through pharmacies in 8-ounce and 32-ounce bottles. Requests for professional literature are invited.

LABORATORY NATIVELLE LIMITED

NORTH CIRCULAR ROAD, LONDON, N.W.2

THE MODERN DECLINE OF BREAST-FEEDING*

BY

J. C. SPENCE, M.D., F.R.C.P.

Assistant Honorary Physician to the Royal Victoria Infirmary, and Honorary Physician to the Babies Hospital, Newcastle-upon-Tyne

Prosperity and social comfort have not encouraged maternal breast-feeding of the human infant. There can have been few women of fashion in the eighteenth century who did not hire a wet nurse to succour and suckle their babies. At that time the wet nurse was the mother-substitute, and failing a wet nurse the mother must feed her own infant or it would die. Now we have changed all that. Since then we have learnt how to feed babies on cow's milk in a simple and relatively safe manner. We have invented the feeding-bottle and the rubber teat. Chemists have shown us the composition of milk, and commerce has made it available for all. We can have it fresh, dried, or condensed. We know how much to give and how to give it in order to promote an infant's growth. The cow is now the mother-substitute, and in this country there is no mother who cannot obtain this substitute if she so desires it. It is therefore an appropriate moment to ask ourselves to what extent there is a decline in maternal breast-feeding, and to inquire into the cause and effects of this decline. If it be found that a considerable proportion of women are gestating and bearing children but are cutting short this reproductive cycle by failing to lactate, it is surely both a matter of biological or clinical importance and a social experiment of great scientific interest.

The clinical importance of breast-feeding has always been recognized by paediatricians; but here again it is an appropriate moment to remind ourselves of this fact, for the infant mortality in this country remains twice as high as that in many other countries, and in some of our industrial towns it remains three times as high as it is, for example, in towns of similar size in Australia. Moreover, in some of our towns it has been slowly rising in recent years in spite of an increase in public expenditure on child welfare. This means that of the 40,000 deaths of infants each year in this country 20,000 might be prevented, or, to bring it nearer home, of the 500 infant deaths which take place each year in some of our industrial towns at least 300 could be prevented. The Edwardian question, "If preventable, why not prevented?" should be sufficient to keep alive our clinical interest in this important subject. That it is important can be recognized by comparing it with the clinical and social significance of a disease like pernicious anaemia. There can be no more than 7,000 or 8,000 people with per-

nicious anaemia in this country, yet the scientific and clinical interest involved in treatment of these old people is out of all proportion to that devoted to the prevention of the 20,000 preventable infant deaths each year.

It may be said that I am pushing an open door, that it is well recognized that an encouragement of breast-feeding is one of the methods of combating the excessive infant mortality. But there are many who do not recognize it. Let me quote a medical officer of health of one of the large towns who has recently written in his annual report: "I have reached the stage when I question very much if there is any material advantage in keeping an infant on the breast. Further, I believe that fewer dietetic troubles occur in the artificially fed babies, because there is less likelihood of overfeeding and irregular feeding and there is greater control of the diet. I have not seen any recent evidence to suggest that the artificially fed child is more prone to disease or more likely to succumb to disease than his naturally fed brother, neither do I think that he is responsible for the large number of rejects found amongst recruits to the national services. Finally, so far as the mother herself is concerned, I think it is to her advantage that she should not feed her child. The whole action of feeding acts as a drain on her resources and curtails her activities over a long period, and certainly does not encourage her to increase the number of her family." There can be no doubt that statements like this encourage the use of cow's milk at the expense of breast-feeding and that they represent a view which is spreading in some sections of the community.

The Incidence of Breast-feeding

Accurate information about the incidence of breast-feeding is difficult to find, and is still more difficult to compare on account of the difference in the methods of enumeration used. We desire to know what proportion of babies in various countries or in different social groups are breast-fed or artificially fed from birth. We desire to know also at what age weaning takes place. It is this precise information that is lacking. Some observers record their results by estimating the average duration of breast-feeding, others the proportion who are entirely breast-fed for six months or nine months. But there is no commonly adopted system of collecting statistics which tells accurately when women wean their babies. From maternity hospitals we can obtain accurate information about the feeding of infants in the first few weeks of life. This in itself is valuable, for in this neo-natal stage

* Read in opening a discussion in the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Plymouth, 1938.

nutrition and protection from inimical influences are more important than at any other age. Moreover, since a large proportion of babies are weaned shortly after this neo-natal stage the incidence of breast-feeding at this time tells a good deal about the trend of events.

In Newcastle Dr. Frank Stabler has made careful statistical studies of the clinical material in the Princess Mary Maternity Hospital in recent years. He has supplied me with the following figures, which represent the percentage of those infants leaving hospital at about the end of the second week of the puerperium who are wholly breast-fed:

| | | | |
|-------------------------|-------|-------------------------|-------|
| 1933 (1,431 infants) .. | 87.8% | 1935 (1,436 infants) .. | 80.9% |
| 1934 (1,460 ") .. | 84.3% | 1936 (1,346 ") .. | 74.6% |

These figures from a city maternity hospital do not perhaps give a fair example of the people, so I have collected information from a private nursing home for middle-class patients and have excluded all patients with obstetrical difficulties or physically defective children. The matron is a sagacious woman with a strong personality who encourages breast-feeding wholeheartedly. Between 1934 and April, 1938, there were 1,046 normal deliveries, and of these 76.8 per cent. of the infants left the home wholly breast-fed, 19.6 per cent. partially breast-fed, and 3.6 per cent. wholly bottle-fed. The majority of infants who are only partially breast-fed in hospitals are shortly weaned, so it is plainly to be seen that in this town satisfactory breast-feeding in the neo-natal period is maintained by only three-quarters of the mothers, and that there has been a significant decline in the incidence of breast-feeding in recent years. In Edinburgh Dr. T. Y. Finlay has made a careful estimate of the incidence of breast-feeding by visits to the homes of three sample groups totalling 3,000 mothers, and has allowed me to use his results. The sample groups agree closely, and show that at the tenth to fourteenth day 87 per cent. of the mothers are wholly breast-feeding their infants.

There is an immediate decline in the incidence of breast-feeding when the mother resumes domestic and social duties. Dr. George Brewis has collected statistics of 1,326 infants who attended the municipal welfare centres in Newcastle in March, 1938. Of these, 58.4 per cent. were wholly breast-fed at three months and 34.7 per cent. at 6 months. In Edinburgh, of the 3,000 mothers visited between the third and sixth months 55 per cent. were continuing to wholly breast-feed their infants and 38.5 per cent. when visited after the sixth month. In both towns the child welfare services give ardent encouragement to the mothers to breast-feed their infants, so the results may be regarded on the high-water mark of achievement in big towns under prevailing conditions. A similar state of affairs obtains in other towns and other countries. In a South Lancashire centre in 1933 Wilson found that 50 per cent. of the infants were weaned at the third month. In an American village Bisal found that only 31 per cent. were breast-fed for three months. In Scandinavia two investigations have shown that 32 to 40 per cent. were breast-fed for six months. In Riga only 19 per cent. were breast-fed for six months. In America conditions wholly breast-fed for six months. In America conditions that breast-feeding exclusively for the newborn is about extinct in Brooklyn amongst the middle-class mothers. Yet in Chicago of 20,061 infants under the care of the welfare service from 1924 to 1929, 48.5 per cent. were entirely breast-fed for nine months.

For our argument it is safe to assume that, apart from the little milk that may be yielded in the first few days, 20 to 30 per cent. of babies are artificially fed from birth

in many if not most of our big towns, and that not more than a third of the mothers of these towns are fully feeding their babies until the sixth month. My experience is that bottle-feeding is a habit which readily spreads. If one woman in a maternity ward resorts to bottle-feeding others immediately begin to find difficulties in their own ability to breast-feed. So under prevailing conditions we can presume that a further decline in the incidence of breast-feeding will take place.

Influence of Feeding on the Infant's Health

The medical officer of health whom I have quoted is not alone in questioning the superiority of breast-feeding over artificial feeding in maintaining the health of the infant, and the belief has spread to other quarters. Modern advertisements and other agencies have persuaded large numbers of women that artificial feeding is entirely safe and satisfactory for their infants and not disadvantageous to themselves. The mother-and-child subject favoured by the mediaeval painters has been replaced by the baby-and-bottle subject or the studio-milkmaid subject of the modern photographic poster.

It is possible that hospital physicians seeing so much of sick infants are apt to exaggerate the dangers of artificial feeding. But, having taken that into account, it is beyond all question that breast-fed infants show a greater freedom from disease and a greater power of recovery from disease than artificially fed infants. The results in pyloric stenosis give straightforward evidence about this. In the Newcastle Babies' Hospital the mortality in 114 breast-fed infants with pyloric stenosis has been 5 per cent., but in 133 bottle-fed infants it has been 30 per cent. But the most complete evidence is to be obtained from the studies of Grulee and Sanford in Chicago. They investigated the morbidity rates and mortality rates in 20,000 infants. Including every minor disturbance of health, the morbidity rate in the breast-fed group was 37 per cent., in the partially breast-fed group 53 per cent., and in the artificially fed group 63 per cent. The mortality rates were still more striking. Of their 9,749 breast-fed infants only fifteen died, of 8,605 partially breast-fed infants 144 died, and of 1,707 artificially fed infants 144 died. These figures are significant enough to require no elaboration. But apart from the immediate significance of high morbidity rates and high mortality rates in artificially fed infants, there may be remote ill effects which have not yet been recognized or defined. It is possible that some of the serious degenerative diseases of adult life have their origin in the artificial feeding of infancy. I know of no investigation of this problem which has been scientifically carried out to disprove this, and we may recognize that such remote results are within the bounds of probability when we recall the wonderful clinical observations of Nye, that temporary exposure of children to the paint on veranda floors of wooden shacks produced arteriosclerosis and chronic nephritis thirty and forty years afterwards.

Breast-feeding and the Mother

There are difficulties in approaching this question of the effects of breast-feeding on the mother herself. Apart from the observation that repeated lactation in non-nourished women may produce anaemia, there is very little scientific information on this subject. It might be suspected that women who have cut short the reproductive cycle by failing to lactate would be prone later to develop endocrine disorders. The pathological obesities which sometimes follow pregnancy suggest that a mismanagement

ment of lactation may be an example of this. In the absence of scientific information opinions appear to be based largely on sentiment.

Much more is known about cows. Out of a common pedigree stock of shorthorn cows the breeders by selection have produced in thirty years two distinct strains—the dairy shorthorn and the beef shorthorn. Intensive breeding of these strains has resulted in a remarkable difference in their milking capacity. The dairy strain of shorthorn is capable of yielding five to six gallons of milk a day. The beef strain is capable of yielding less than two gallons of milk a day. So far has this gone that there is a danger that the beef-strain shorthorn will become incapable of yielding enough milk for her own calves. Selective breeding from human beings who hold the view that breast-feeding is no longer necessary may have remote biological effects we do not foresee.

The effects of lactation on the mother's character, temperament, and mental outlook deserve equal consideration with the physical or biological effects. This aspect has received very little study. Modern novelists, eager as they are to explain every conscious and subconscious gesture of their subjects, have hardly touched the theme. Havelock Ellis in his *Psychology of Sex* gives it relatively little notice. Yet the puerperal period is characterized by most interesting and distinctive psychological reactions. The desire for a mother to be left alone to sleep immediately after parturition has both a physical and a psychological value. And afterwards her peculiar jealousies and her craving for individual attention both suggest that she needs a special environment, for psychological as well as physical reasons. Again, if one is to judge by the look of lascivious content that comes over some women's faces as they feed their infants there must be a sense of achievement in the act which has a definite value in maintaining their mental health. These mental states and emotional states of the lying-in woman deserve careful elucidation. Most of those whose profession it is to research or to write are debarred either by their sex or by their sterility from judging aright in this matter. But there are some who are equipped by experience and insight to undertake this work, and I would suggest that they should elucidate these problems for us. For my part I can say only that in most cases I can recognize a woman who has successfully breast-fed an infant, and that I find her to be a saner and a more sensible woman than her sister who has failed to do so.

The Physiology of Lactation

If we are to discuss the causes of failure in breast-feeding it will be well to consider first the mechanism of lactation. New knowledge of the ovarian hormones and the pituitary hormones has filled many gaps in our understanding of this. During pregnancy the ovarian hormones develop and increase the breast tissue and the nipples, which in this way are prepared for lactation. Immediately after parturition the ovarian hormones which inhibit lactation recede, and a pituitary hormone, "prolactin," then comes into play and establishes lactation. Later lactation is maintained by this pituitary hormone secreted under nervous reflex influences. There are at least two of these reflex influences. The first is the frequent emptying of the breast by suckling; the second is a nervous influence engendered in the emotional state of the mother and probably acting through the hypothalamus. Fear, doubt, anxiety, and lack of interest are states of mind which inhibit lactation. I have known a woman to be secreting daily thirty-five to forty ounces of milk for her infant

and yet the yield has fallen suddenly to three or four ounces a day under the influence of a dispute with the father of the infant. In my experience it is emotional disturbances in which the father is concerned that have the greatest inhibiting effect, but over-anxiety about her own ability to feed her infant is almost as harmful. The behaviour of the father during and shortly after the mother's parturition, although often a subject for ridicule, is significant enough to suggest a remnant of some remote biological purpose, and as such it has been studied by the anthropologists. For our purpose it is sufficient to say that in the early stages of lactation he should remain an admiring and protective figure in the background, while his wife receives the ministrations and exhortations of a sagacious and experienced woman.

Studies of mothers' behaviour after parturition indicate that it alters in three distinct stages, each of them with a bearing on lactation. The first stage is one of profound rest and relaxation both for mother and child which may last for twenty-four to forty-eight hours. The child should not need milk or other fluid in that stage, and the mother should be free from meddlesome interference. It is one of the most miraculous of physiological arrangements that lactation is delayed in that early period and afterwards is suddenly established simultaneously with the awakening child's desire for food. The second stage is the establishment of lactation. This may take five or six days, and corresponds to the physiological lying-in period. In this stage the mother will require the help of the modern equivalent of the experienced and sagacious woman. Between these two the establishment of lactation should be a co-operative function, with the mother being allowed to fondle her child as often as she wishes, and without any fixed rules about four-hourly or three-hourly intervals. Another feature of this stage is that the mother requires to be segregated and free from distractions. She should, if possible, be in her own room, concerning herself only with the joys and duties of recovering from her labour and launching her infant on its new mode of existence. Studies of the peculiar jealousy reactions of lying-in women indicate the physiological need for this segregation. If in a surgical ward there are twelve women who have recently had operations for appendicitis we observe no jealousy and no unusual behaviour when a nurse gives particular attention to one of their number, but if there are twelve women in a maternity ward, all recently delivered, and a nurse has to give particular attention to one of them, there is immediately an atmosphere of jealousy which shows itself in demands for bed-pans and for other forms of individual attention. The third stage follows the lying-in period and begins when the mother, now out of bed, takes the feeding and care of her infant into her own hands. In these days its commencement, for many women, corresponds with the day of their discharge from a maternity hospital, abruptly to shoulder the double task of tending to their infants and their homes. Too often the significance of these stages and the need for the mother to pass successfully from one to another is overlooked. Particularly in maternity homes and by maternity nurses are they overlooked. For ten or fourteen days the mother follows the ritual of a hospital bed-patient with her infant presented to her at the ordained intervals, and then on the next day full responsibility is suddenly transferred to her.

There are wide variations in the time and rate at which lactation is established. This is well recognized, but it is not sufficiently understood that lactation may have been prevented for several weeks and yet be re-established. I have seen it re-established eleven weeks after parturition

in a woman who has resorted to bottle-feeding her infant, and who had not previously secreted any breast milk either by suckling or by manual expression.

There is a good deal of misunderstanding concerning the chemical composition of human milk. Fantastic theories of infant feeding have been built on the supposition that it is a food containing fixed and optimal quantities of protein, fat, and sugar. Far from being fixed, there is considerable variation in its composition from one feed to another. The fat content of human milk is commonly 3 per cent. at the first feed of the day, 6 per cent. at the second feed, and between 4 and 5 per cent. at the later feeds. The protein and sugar contents vary also, but to a lesser degree. Even the volume of feeds fluctuates widely under natural conditions. A healthy baby may require and take six ounces at one feed and be satisfied with three ounces at the next. I wish to emphasize these facts, for I shall refer to them again when dealing with the causes of failure in breast-feeding.

Concerning the normal mechanism of lactation there remains one other question. What percentage of women are incapable of breast-feeding because of physical abnormalities? Less than one cow in a thousand fails to lactate. Is the greater number of women who fail due to inherent structural faults or to environmental causes? In many rural districts in this country at least 95 per cent. of women successfully establish their lactation. There is no reason to think that with proper management the proportion of urban women capable of doing this is less than it is among the rural women. An endocrine mechanism which has allowed a woman to conceive and give birth does not at that stage fail to provide for lactation. There remain a few, less than five per cent., in whom it is physically impossible to establish lactation either because of diseased or malformed nipples, or because the infant cannot suck on account of mental defect or of cleft palate or other physical fault. All women who are not handicapped by these physical defects can breast-feed their infants if they desire to do so and if they are not prevented by an unsuitable environment.

The Failure of Lactation

There are those who cannot, those who will not, and those who know not how to breast-feed their infants.

Those who cannot I have already mentioned. They are a small group with physical faults in themselves or in their infants. Those who will not breast-feed their infants I shall not discuss, except to say that often the fault lies not in themselves but in those who advise them. It is due as much to ignorance as to selfishness. It is fostered by a belief that bottle-feeding is adequate and breast-feeding no longer necessary. Modern methods of advertisement are responsible, but the fault lies also in the readiness to receive advice and the desire which lurks in everyone to give advice about health and to appear possessed of occult secrets when giving it. The medical profession itself is not free from the influences of advertisement. No doctor receives a blotter once a week advertising breast milk. Too often do we hear of advice being given from within the profession that an infant must be weaned because the breast milk is not agreeing with it—advice portentously linked with a recommendation of a special brand of infant food, suggesting again the possession of a secret knowledge of the biochemical advantages of that brand of cow's milk over human milk for an infant who later may be found to be suffering from pyloric stenosis. More recently another kind of belief has arisen which encourages the weaning of babies. It is a belief

that has grown out of the publicity about malnutrition and extra nourishment. It was illustrated for me by a young wife living on a completely adequate diet, who told me that she could not breast-feed her infant because she was not receiving "extra nourishment" from a welfare centre. For this reason she had weaned her baby. The need for adequate nourishment of nursing mothers is obviously important, but here was a woman, typical of many in this country, muddle-headed by what she had read. In its effects this ignorance is the same as the selfishness of the young wife who will not feed her infant and explains it by saying that her husband wishes her to go about with him and does not like her to breast-feed—the wife who sacrifices the role of mother to that of mate.

It is those who know not how to breast-feed and fail in spite of their desire to do so who deserve our close consideration in this discussion. This failure ordinarily takes place chiefly in two stages. The first is in the lying-in period, through difficulties in establishing lactation. The second is shortly after the lying-in period, through difficulties in maintaining lactation.

I believe the chief cause of failure in establishing lactation is due to mismanagement. To explain this I can do no better than quote from a letter from Dr. Clifford Grulee: "My personal opinion is that all this talk of the modern woman being unable to nurse her baby is due very largely to the modern nurse's tendency to poke a bottle of milk in the baby's mouth, which of course is due to the indifference of the physician." He goes on to describe that in one of his hospitals they have two services for the newborn. In one, the out-patient service, 95 per cent. of the babies were being breast-fed at the end of the lying-in period. In the other, an in-patient department, less than 50 per cent. were breast-fed. They have been able to raise this to almost 90 per cent. simply by refusing to give the child a bottle in the first week of life. If fluid is required a little is given from time to time from a medicine-dropper. The attitude of the nurse at this stage is of supreme importance. I know of one maternity nurse who, after having been in practice for fifteen years, came to a household in which she was first enthused about breast-feeding and then instructed in overcoming the difficulties of establishing it. Prior to that more than half her babies had been bottle-fed. When seen a few years afterwards she proudly proclaimed that since her sojourn in that house she had never failed to establish breast-feeding. The essence of the faults in most hospitals and nursing homes is that they attempt too much to mechanize breast-feeding. They have institutional rules about the times of feeds, the amount of feeds, the weighing of babies, and the test weighing of feeds, to which they try to fit the patient. If this is not successful anxiety is aroused, and immediately the difficulty of establishing lactation is increased. I heard recently of a woman troubled much by insomnia throughout her pregnancy who was delivered of her child in the early hours of the morning and then fell into a satisfactory post-partum sleep, to be awakened at seven o'clock to have her teeth brushed. The lying-in room is becoming too much a combination of a sick-room and a flower-decked reception room. After lactation has started the mother should be allowed to fondle her child as often as possible. There should be no test-weighing of the feeds and no temperature-taking of the infant unless clinical observation indicates the need for it. And there should be no feeding of a healthy newborn baby with a bottle until the first week at least has passed and it is proved that the breast

milk is inadequate. Finally, in houses and hospitals each mother should have her own room. If this can be afforded for the inmates of prisons it should be possible to afford it for the mother of babies. In her own room she would be free not only from the contagion of bacterial disease but also the contagion of desire to bottle-feed which at times spreads from mother to mother in a big ward.

Probably the most important cause of failure to breast-feed among those who desire to do so is the temporary inhibition of lactation which occurs shortly after the lying-in period when the mother returns to her household duties. This is interpreted as a final disappearance of the milk, with the result that she resorts to bottle-feeding. This could be overcome to a large extent by allowing the mother to be out of bed for a few days in the hospital before returning home, and by warning her that the disappearance of the breast-milk will probably last only for a day or two and that it can be restored with perseverance. I shall quote one more example to illustrate the faults of the mechanization of breast-feeding. Some time ago I was summoned to the house of young parents to see a three-months-old infant. The father was a lecturer in science, the mother a recent graduate of a university. The bookcase in unstained oak, the bare off-white walls, and the weekly political journals denoted their type and tastes. She was an earnest woman, breast-feeding her infant and anxious to continue. The complaint was that the child had failed to gain weight for a month and was but little over its birth weight. It was much troubled by frequent green stools and restlessness. I suggested that the child had no disease, but was receiving too little nourishment. This was denied by the mother, who produced figures and charts to show that test weighing had been used for every feed since birth, and that the infant had received the exact physiological amounts of breast milk—so many ounces a day for each pound of its body weight. She quoted authorities at me to prove her point. I persuaded her to discard the test weighing and to feed the infant five or six times a day until he appeared satisfied. In ten days he gained a pound, and there was no more trouble and no more test weighing. This over-mechanization is again seen in the frequent appeal to know whether a baby should be fed at four-hourly or three-hourly intervals. I would submit that the reply to this should be that the mother should cultivate an instinctive recognition of her own baby's needs, that she should come to know when the baby is satisfied, and that she should then choose the times of feeding most suitable to herself and her child. Only in difficulties should professional advice be sought.

Conclusion

It appears that the incidence of breast-feeding is declining. The causes of this are our increasing indifference to the value of breast-feeding and a mismanagement of the mother in the early stages of lactation. The correction of the fault lies mainly in the hands of those who tend and advise the mother in and shortly after her lying-in. Big hospital wards and crowded child welfare centres do not provide an atmosphere which encourages breast-feeding. Better education of doctors and maternity nurses in the care of infants may help to correct the fault; and that the importance of this education is not sufficiently recognized is suggested by the recent authoritative order of the Ministry of Health that panel practitioners attending their refreshing postgraduate courses are not to receive instruction in diseases of infancy or childhood.

THE SPREAD OF STREPTOCOCCAL DISEASE

BY

W. H. BRADLEY, D.M.

Department of Medicine, Cambridge

Studies in the epidemiology of streptococcal disease are appearing with increasing frequency, and during the past ten years certain new principles have evolved concerning the prevention of these infections. Clinical practice has, however, been slow to apply these important principles. The obstetricians, stimulated by public anxiety concerning puerperal sepsis, have made valuable contributions to these studies, and the story of their success has recently been told by Professor Miles H. Phillips (1938); but the rest of the profession would appear to lag behind both in practice and in teaching. This is unfortunate, because in some quarters the obstetrician's particular interest in puerperal sepsis has given a specialist bias to a problem of general concern. For puerperal sepsis accounts for a small part only of the total morbidity and mortality attributable to *Streptococcus pyogenes*, and it seems not improbable that the practice of obstetrics is, in fact, less affected by the droplet spread of streptococci than are the other branches of clinical medicine and surgery. From the public health point of view it matters little through which portal the streptococcus or its toxins invade the body, and it is not always realized that what is written about the prevention of puerperal fever applies also to all disease spread by droplet contagion. But since puerperal fever has established itself as the classic type of grave streptococcal disease *sine eruptione*, it might be well for us to read again Phillips's historical note and add "*et alia*" after each mention of puerperal fever: for what applies to the classic type is equally applicable to scarlet fever, erysipelas, cellulitis, most wound infections and septicaemia, the bulk of nasopharyngeal and otic suppuration, many pneumonias and, probably, acute rheumatism and acute nephritis.

The crux of the whole matter is a paradox: an isolated case of puerperal fever is in itself evidence of an epidemic. It implies a widespread prevalence of streptococcal disease, and a slight rise in maternal mortality is paralleled by a much greater toll from other streptococcal accidents. If puerperal fever is preventable so are these other accidents, and information as to how they can be controlled is rapidly accumulating. Let us review some of the more recently established facts.

Bacteriology of Streptococcal Infections

Old nomenclatures are a hindrance. Okell's (1932) Milroy Lectures provide a good text. We are now concerned almost entirely with *Streptococcus pyogenes*, for this is the group most commonly pathogenic to man. *Str. viridans* and non-haemolytic organisms, apart from an occasional strain of *Str. pyogenes* which fails to give β haemolysis, are, except when they invade an unusual location such as a previously damaged endocardium or urinary tract, of little significance as disease producers and must be looked upon as part of the normal bacterial flora of man. The part played by anaerobic streptococci is not yet measured, but on clinical grounds it would appear to be of minor importance. The classification of haemolytic streptococci—and for our present purpose it is safe to say that we are almost entirely con-

cerned with those giving β haemolysis on horse-blood-agar plates—has been simplified by the introduction of serological typing. No longer does definition of a given organism depend on its morphological and cultural characters, which now become of academic interest only. We can forget such names as "*Streptococcus longus*," "*Str. brevis*," and "*Str. mucosus*." We can also forget *Str. epidemicus*, *Str. scarlatinae*, *Str. erysipelatis*, *Str. anginosus*, etc., and with them discard the "specificity" hypothesis which sought to associate a well-defined clinical entity with a particular and specific kind of organism. We now know that in any given epidemic a single strain of *Str. pyogenes* may produce angina, scarlet fever, erysipelas, cellulitis, lymphangitis, adenitis, otitis, sinusitis, meningitis, puerperal fever, septicaemia, etc. What Okell (1932) calls the "unitarian" hypothesis is now well tried, and must be accepted if we are to understand the very elements of streptococcal epidemiology.

The bulk of, but not all, haemolytic streptococci pathogenic to man are identifiable by a specific carbohydrate substance, and fall into Group A of Mrs. Lancefield (1928). This group is further subdivided into about thirty different "Griffith types" (Griffith, 1934), each characterized by a specific "M" substance upon which their identification by agglutination with absorbed sera depends. It is this typing technique which has made epidemiological studies and the proof of the unitarian hypothesis possible. A note of warning must be introduced here. These techniques are available in very few laboratories, and it is at present unfair to expect the majority of bacteriologists to undertake Griffith typing.

Epidemiology

The most striking epidemics of streptococcal infection are milk-borne. They are of comparatively common occurrence and are so impressive that they are believed by some to be the main source of spread. This is undoubtedly untrue, and in the epidemics about to be described no evidence of a food vehicle was found. Epidemiology is an ecological study, and the behaviour of an epidemic is influenced by its environment. For this reason one should hesitate to draw conclusions from isolated observations in time or space, and should be careful to pool as many experiences as possible before making deductions. The examples about to be described should be added to the pool, but as preliminary investigations they are of value because they deal with three distinct types of community. (1) *The semi-isolated community*: In this case a boarding school for boys in which contact with the outside world is limited and presumably the opportunity for introduction of new infection considerably restricted thereby. (2) *The general hospital*, in which the bacteriological environment of the inmates is particularly complex, since individuals living therein inevitably make contact with more diseased persons than they would meet with in their homes or elsewhere. (3) *The family*, which is probably the simplest unit of all and as such might well be the most satisfactory material for the study of a problem in clinical epidemiology.

Streptococcal Infection in a Boys' School

In Fig. 1 are given in graphic form the bacteriological findings from all upper-air-passage infections requiring more than twenty-four hours' exclusion from school in a community of about 320 boys during the years 1931 to 1934. The graph also includes the years 1929 and 1930,

but during this period bacteriological observations were incomplete. It will be seen that during the six years dealt with six different types of streptococcus became established and gave rise to the spread of disease. The main incidence of disease was in the Lent terms. In 1931 there suddenly appeared a new type of organism which gave rise to sixty-three cases. Nine other positive streptococcal cultures were obtained: one belonged to the type of which the school had had previous experience, and eight were unidentifiable. They may not have been Group A organisms. *Str. pyogenes* was not recovered from forty-one cases, and it was clear that streptococcus Type 18 gave rise to the bulk (60 per cent.) of the cases encountered in the school at this time. In the following term (1931, II) one case only of Type 18 infection was

FIG. 1.—Serological types (Griffith) of *Streptococcus pyogenes* producing nasopharyngeal infections in a semi-isolated community (boys' public school, population 300 to 320).

found, although about the same number of non-coccal infections occurred in the school. Streptococcal fever had almost disappeared. In the third term of 1931 a new type of organism, Type 13, was first detected, and continued to produce disease for five consecutive terms. In the last two terms (1932, III; and 1933, I) a number of carriers of this organism were discovered, and were detected occasionally until the Lent term of 1934. (Their presence is indicated by a small circle "o" in Fig. 1.) Type 13, however, seemed to have either lost its power to become epidemic or the school was effectively immunized against it.

During the Lent term of 1932 another type of organism, which had at that time not been included in the Griffith classification and which is indicated in Fig. 1 as Type "X," made its appearance and gave rise to the bulk of the disease affecting the community. It appeared again at the end of the year, since when it has not been encountered. Type 1, a well-recognized scarlet fever strain, was first recovered from the throat of a new boy who showed no signs of disease, and it was not until fifteen months later that clinical cases of Type 1 infection

began to occur, and gave rise to an epidemic of forty cases of nasopharyngitis.

Although during the two subsequent terms four carriers of Type 1 were encountered, no further epidemic spread of this organism followed. At the beginning of the second term of 1933 a wave of non-streptococcal colds occurred. A month later, on June 11, in brilliant summer weather, a single case of scarlet fever appeared. Streptococci were not discovered in the throat, and the portal of entry appeared to be a trivial scratch on the boy's foot. It is interesting to record that a streptococcus giving a clinical picture very suggestive of Type 1 caused an epidemic in a neighbouring village during October and November, 1933, and there was some evidence that the infection had been carried by a school servant and had been kept going through the medium of one or two apparently sporadic cases of sore throat seen during the summer months. At the beginning of 1934 Type 6 gave rise to a small epidemic, and was detected in the school during two terms, after which it completely disappeared from the community; during 1935 and 1936 there was no epidemic spread of streptococcal disease, this organism having apparently been replaced by pneumococci.

It is tempting to speculate further upon the immunological implications arising out of Fig. 1. It was quite certain that infection with, let us say, Type 18 gave no immunity against infection with Type 13; in fact, there were some boys who reacted to all six types of infection. Other boys, although equally exposed, reacted to none. It is also possible that as the result of so many contacts with streptococci some form of group immunity had begun to result by 1933 and was effective in 1934 and 1935, when the health of the school was unusually good, but this improvement was more closely associated with a deliberate attempt to improve the hygienic conditions within the school by reducing, in September, 1933, the number of the community from 340 to 230 boys, and thereby attaining much more effective spacing in dormitories, classrooms, and playrooms.

The six epidemics described showed certain features which have now been seen so frequently that they may be considered almost characteristic of the epidemiological picture produced by the droplet spread of streptococci. Two of the epidemic periods have been described in greater detail elsewhere (Bradley, 1932a, 1932b), and can be compared with the observations of other workers (Glover and Griffith, 1931). Furthermore, one may conclude that streptococcal disease, unless milk-borne, spreads slowly and does not give rise to steeple-like epidemics or overwhelm communities with dramatic suddenness. The maximum incidence in the Lent term has already been referred to. Three or four weeks of a term often elapsed before cases occurred with sufficient frequency to cause anxiety of epidemic spread, and another month had passed before the epidemic had reached its peak, after which the decline in case incidence was gradual. The spread of infection was intensified by the simultaneous presence or previous occurrence of other catarrhal disease such as "influenza," non-coccal colds, or measles, the last-mentioned having a marked effect in elevating the passage of streptococci. The complications of influenza and measles were attributable to the streptococcal types producing coincident infection in the sick-rooms. On one occasion thirteen boys, with negative throat swabs at the time of admission to a sick-room for a non-coccal pyrexial nasopharyngitis, were brought into contact in the same ward with a boy suffering from primary streptococcal

fever. Five of the thirteen, occupying beds adjacent to that of the streptococcal case, contracted secondary streptococcal disease; and a sixth, occupying a bed on the other side of the ward, also became involved (Bradley, 1932b). This is one of many similar examples in which ignorance allowed grave disease to spread among already sick boys. A more enlightened physician would have prevented the introduction of a streptococcal case into a non-streptococcal ward, and so have avoided a fatality. At present such a mistake can be excused because it requires extensive clinical experience to distinguish between streptococcal and non-streptococcal nasopharyngitis without bacteriological evidence. There are, however, no practical difficulties, cost excluded, against the immediate application of simple bacteriological techniques to this problem. Failing such aid, and even in epidemic times, every boy with nasopharyngitis of unexplained aetiology must be looked upon as a danger to the community and nursed on the barrier system until it is proved that he is not suffering from an infection not already involving his fellows.

It will be seen how during each term one, and occasionally two, types of *Str. pyogenes* established themselves and gave rise to epidemic disease, so that towards the middle of the term the flora of the school had become fairly constant, and the bulk of infection encountered was attributable to one Griffith type. Some months later another type would appear and apparently overgrow its predecessor. The latter would be recovered occasionally only, was not the obvious cause of new disease, and was apparently residing in an immune carrier. Strangely enough, these carriers did not start off new epidemics—possibly because, in a closed community, they were living in an immunized population. If this suggestion is tenable it is strong evidence that a person immune to one Griffith type is not protected against invasion by another. He will, however, be partially or completely protected against the rash-producing Dick toxin, which is produced in varying amounts by most, if not all, types of *Str. pyogenes*. The incidence of scarlet fever is therefore fortuitous and is no measure of the extent of streptococcal parasitism.

It may be assumed that there were six emergency periods when new infection was introduced to the school, and it is probable that had intelligent action been taken when first these infections were detected much of the sickness in the school could have been averted.

Spread of Streptococci in a General Hospital

These studies have been attempted in a provincial hospital. They are not comprehensive, since it has at times been difficult to obtain information regarding the occurrence of P.U.O. or nasopharyngitis, and in certain wards the investigations have, for one reason or another, been partial or inadequate. It is, however, probable that Fig. 2 is significant for about 120 hospital beds, mainly in the medical wards. During the twelve months beginning November, 1936, six types of *Str. pyogenes* gave rise to multiple cases of infection contracted during the patients' stay in hospital. Fifty such infections were observed, in seventeen of which scarlet fever, due to four Griffith types, was diagnosed. Two deaths were directly attributable to these infections; two other infected patients died prematurely. The problem is therefore one of considerable importance. The obstetrical, and ear, nose, and throat wards were not included in the investigation, and scant attention was given to the surgical wards. Yet it is in the last that ward infections with *Str. pyogenes* are known to do most damage. The hospital under

observation is well spaced and well equipped; the hygienic conditions are above the average. Fig. 2 attempts to show the probable direction of spread, but it is obvious that some intermediaries between the homologous cases were not detected, and that the lines of spread indicated in

Yet the tendency was to relate the scarlet fever to a common source of infection, although, in fact, four distinct sources were responsible, one of which could be traced to a child admitted to the hospital with otitis media from a home from which two children had been removed to isolation with scarlet fever during the preceding fortnight. In three of the epidemics there was evidence that nurses had acted as intermediaries in the transmission, but there was nothing to suggest that nurses had been more active than other people in introducing the infection into the hospital in the first instance. Furthermore, where the spread was sufficient in amount to allow for deductions the evidence pointed rather to inter-bed spread. One of the most striking features of these infections was that they ended as suddenly as they began, although no special action was taken to control them. In two cases the spread came to an end immediately after dissemination to other wards had been observed.

Fig. 3 represents the picture from September, 1937, to January, 1938. During this period four and possibly five more infections were introduced.

We then tried to identify the source of the organisms, a fair picture of streptococcal flora of the hospital having been established during the previous months. Two cases of Type 25 infection followed the introduction of this type in a patient suffering from quinsy; a case of cellulitis gave rise to fifteen secondary cases of Type 6 infection. The routes of spread of Types 22 and 6 have been extracted from Fig. 3 and represented separately in Figs. 4 and 5. The Type 11 infection was apparently introduced by a patient with suppurating cervical glands; two of the secondary cases also had suppurating of the glands of the neck. It is not improbable that two Type

the diagram are in some instances guesswork. In the absence of an investigation of this type it would have appeared to a casual observer that scarlet fever was endemic in the hospital. Occasionally cases of scarlet fever were grouped, but more commonly it was impossible to associate them with other cases of this exanthem.

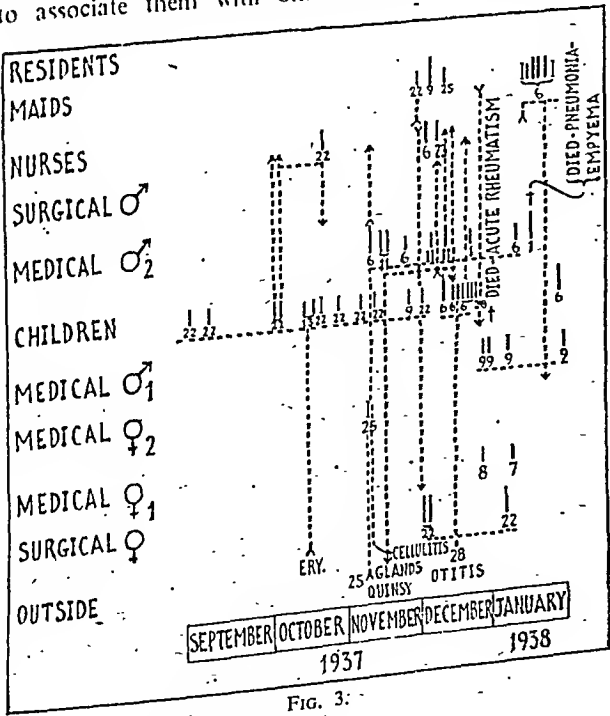

FIG. 3.

28 cases followed the introduction of this organism into the babies' ward by a case with otitis media due to the same type of streptococcus. A bacteriological "cross-section" of the hospital at this time, shall we say at the middle of December, would have shown an extremely complicated picture, since six types of infection were present, and it would have been impossible to draw conclusions from such an investigation. Other workers who have attempted to unravel this problem by serological methods have been disappointed by their results, not improbably because they have attacked the problem at a time when droplet infections of all sorts were particularly rampant. From Figs. 2 and 3 it is reasonable to conclude that the introduction of much of this disease to the hospital could have been avoided by the proper isolation of known cases of streptococcal disease, and that a considerable amount of dissemination could have been controlled had there been proper exclusion of nurses and doctors suffering from acute nasopharyngeal infections. At no time was there any need to postulate a chronic carrier, all spread being accounted for satisfactorily on the assumption that ambu-

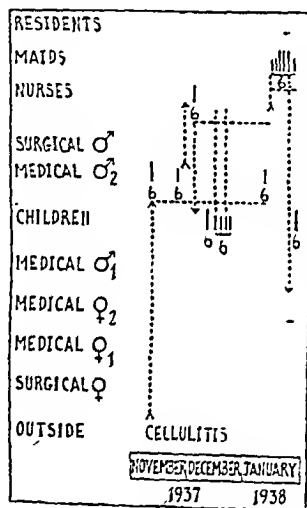

FIG. 5.

Scarlet fever
 Scarlet, sine eruptione
 Cold or sore throat
 6 = Griffith type of *Streptococcus pyogenes*

lant cases of or convalescents from acute nasopharyngitis were responsible. Again, in these hospital studies the slow tempo of streptococcal droplet spread is demonstrated. Three only of the fifty-one attacks of nasopharyngitis or P.U.O. represented in Fig. 3 were associated with erythematous rashes, and in none of these three cases was a diagnosis of scarlet fever made, although, of course, all the fifty-one cases (most of them being trivial in character) were potentially as dangerous to the community as fifty-one cases of scarlet fever.

In this connexion attention is drawn to Appendix A of Sir Arthur MacNalty's report on the state of the public health (1936), as it is probable that patients discharged from infected wards of a general hospital during epidemic times do considerable damage in their homes. Actually only three returned cases came to my knowledge. It will be appreciated that each small wave of infection was a separate problem, and that efficient prophylaxis at the very beginning of each wave would have made a considerable difference in the morbidity from these troubles.

Family Epidemics

There is considerable clinical evidence that the inhabitants of a small rural village will behave in much the same way as a semi-isolated community. In a larger population—for example, a county town—perhaps two or three types of streptococci will spread, while in a large city almost all the Griffith types may be encountered at different times during a period of twelve months. Thus the cultures obtained from fifty-six streptococcal infections in New York City during the first four months of 1936 fell into sixteen of the Griffith types (Bradley, 1937), and I am informed by Drs. Coburn and Pauli that during 1937 all the Griffith types were found to be producing disease in New York City. When, however, individual families are studied it is observed that the disease produced during a family epidemic results from one type of infection only, and many examples of this have been recorded elsewhere (Bradley, 1937). For the purposes of the present discussion one or two examples will serve to illustrate this point.

Case 1.—On February 20, 1936, a girl aged 12 contracted a pyrexial sore throat which lasted a week. On February 27 her brother, 15 months old, became ill, and later developed bilateral otorrhoea, and was under observation for mastoiditis. On February 28 another brother was taken ill with a cold, and ran a fever for three days. On March 3 the first patient, a known rheumatic subject, was admitted to hospital, where she developed an attack of carditis and polyarthritis which ended fatally. Type 6 streptococci were found in profusion in the throats of these three patients. Their mother had suffered a trivial sore throat on February 29, but throat cultures were free from haemolytic organisms by March 3.

Case 2.—In another family a girl aged 4 was removed to an isolation hospital on February 1, 1936, with a diagnosis of diphtheria, but was sent home on February 14, some doubt having been cast on the diagnosis. Two days later one brother developed a severe pyrexial cold with otitis, and after two more days another brother had a bad cold. The mother and a fourth child made no complaint of ill-health, but all five members of the family gave a profuse growth of Type 22 *Str. pyogenes*, and one boy developed an attack of rheumatism five weeks later, while still under observation.

Case 3.—On March 2, 1937, Gwendoline, daughter of a farm labourer in an English village, went to bed with a bad cold and felt ill until March 8. On March 7, however, she got up because her mother was delivered of a baby, the eighth in the family. She helped nurse her mother, who on March 10 became suddenly ill with puerperal fever associated with a scarlatiniform rash, from which she eventually died. Fourteen days after the onset of the mother's illness the father had "influenza," and Evelyn, aged 4, contracted a severe cold two days later, while still five days later, on April 1, Gladys, aged 17, had a cold, and on April 7 Fred, aged 14, contracted "influenza." On April 6 Gwendoline was troubled with pains in her lower abdomen, which persisted for three days. She was vaguely unwell until April 9, when her illness declared itself as typical rheumatic fever. Type 15/17 streptococci were recovered from the throats of four of these patients, but were absent from the mother's throat. A pure culture of this organism was, however, obtained from the pus in a pelvic abscess subsequently operated upon.

The mention of rheumatic fever in each of these histories results from the fact that the starting-point of an inquiry into these family epidemics was the study of that disease. A study of otitis media or scarlet fever or cervical adenitis might have called attention equally well to these family epidemics, and a similar state of affairs will be discovered in almost every family from which a case of streptococcal disease is admitted to hospital. Without doubt disregard for these apparently trivial colds and sore throats has defeated the existing legislation for the control of puerperal and scarlet fever, erysipelas, etc.

Discussion

This paper is mainly concerned with the epidemiological information forthcoming from the application of Griffith typing. Suggestions for the control of droplet spread are not made, for they depend to some extent on certain clinical aspects of the problem which will be discussed in a subsequent paper. Certain conclusions may, however, be drawn from the data presented:

1. The unitarian hypothesis outlined by Okell must be adopted.

2. With a few exceptions streptococci pathogenic to man fall into one group (Mrs. Lancefield, Group A), identifiable by a precipitin reaction with a carbohydrate "C" substance extracted with HCl. An organism not giving Group A "C" substance is in all probability, but not conclusively, not pathogenic to man. These human pathogens are divisible into about thirty Griffith types, which breed true in epidemics and are probably distinct and immutable antigens. They are identified by agglutination with absorbed sera, the latter reactions probably depending on a type-specific "M" substance. There is evidence that the clinical picture produced by some of these types varies in certain details from that produced by others.

3. The rash of scarlet fever must be looked upon as entirely fortuitous in its occurrence and as of little value in the assessment of streptococcal parasitism. The occurrence of rash depends on the coincidence of two variable factors: (a) a Dick-positive patient infected by (b) an organism with a high Dick-toxin content. The idea that scarlet fever is sometimes highly contagious and sometimes hardly contagious at all requires revision. The reason for this idea is now obvious.

4. Scarlet fever is, however, a most useful indicator of the existence of streptococcal disease in a community. Erysipelas, most puerperal fever, cellulitis, the bulk of otitis, and certain types of tonsillitis are similarly useful clinical indicators.

5. The aggregate of these indicators probably represents not more than one-half of the morbidity due to *Str. pyogenes* infections.

6. Present knowledge suggests that the great bulk of streptococcal disease (even when apparently sporadic and unassociated with a high incidence of *pyogenes* morbidity) is zymotic in character and associated with a raised carrier rate of streptococci, the enhanced parasitism being due to one type or, at most, a few types of organism in any one community at any given time.

7. Apart from occasional milk-borne spread, a striking phenomenon easily recognized in most instances, the bulk of streptococcal disease is transmitted by droplet. This common type of droplet spread has certain peculiarities. (a) It is a community disease. Spread within home, school, or other institution accounts for the greater part of the contagion. Casual contacts in street, vehicles, and shops, or from visiting relatives in the case of hospital patients, are relatively of minor importance. (b) Its tempo is comparatively slow, probably because transmission is mainly through immune carriers or subclinical cases. Often five and sometimes ten days elapse between the detection of even the most trivial infection in home or hospital ward. (c) The bulk of vector immune carriers are infected for a short period of time only. These transitory carriers must be distinguished from, and are probably of much greater importance than, persons suffering from chronically infected foci.

8. *Streptococcus pyogenes* is almost ubiquitous in temperate zones, and to many it presents an enormous and unassailable problem. These difficulties are simplified by the knowledge that a number of distinct serological types of organism are at work, each acting as a separate unit. Preventive measures might succeed in controlling some if not all, of these units.

9. In practice, investigation and prophylaxis will start with the detection of one of the many clinical indicators mentioned in conclusion No. 4. If adequate steps are taken at the time of detection of a new Griffith type in any family or community there is a reasonable chance of aborting epidemic spread.

10. Legislation exists for the quarantine and isolation of three only of these clinical indicators. The existing rules are notoriously ineffective, and new regulations with corresponding legislation must be evolved. Isolation and other hospitals admitting acute streptococcal disease are, under present conditions and because of cross-infection (Allison and Brown, 1937; MacNalty, 1936) a potential source for the dissemination of new infections throughout a community.

11. Knowledge of immunological problems relating to *Str. pyogenes* is very incomplete, but it is probable that little or no cross-immunity or group immunity is conferred by infection with any one Griffith type, although homologous immunity probably persists for a considerable time after infection. Immunity to Dick toxin does not imply immunity to streptococcal infection and invasion.

12. A type-specific epidemic tends to run its course through a community and to die out spontaneously. Persistence of an epidemic or the occurrence of relapses should suggest the presence of another type of infection.

13. Control over streptococcal disease will not be obtained until it is realized that *Str. pyogenes* is one of the more common causes of colds, sore throat, and "flu." On the other hand, *Str. pyogenes* tends to spread more rapidly in a community already involved in an epidemic nasopharyngitis due to some other cause—for example, measles. The occurrence of streptococcal complications in measles and similar non-coccal infections is almost without exception part of a separate epidemiological problem. The presence of the complicating organism depends on a zymotic infection coincident with, yet independent of, the primary measles or other nasopharyngeal infection. The bulk of recent evidence contradicts the idea that organisms producing complications were already present in the patient before the attack of measles, etc.

14. Control does not necessarily depend upon complicated bacteriological techniques. Clinical methods are of greater fundamental value and must not be ignored.

I am grateful to the Medical Research Council for a personal grant enabling this work, to Dr. F. Griffith and his colleagues at the Ministry of Health Laboratories for technical advice and assistance, and to the staff of Addenbrooke's Hospital for clinical facilities.

GLUCOSE-TOLERANCE CURVES IN 500 OBESE CASES*

BY

DENNIS EMBLETON, M.A., M.B.

Bacteriologist, University College Hospital

The series consists of 242 males and 258 females. All the subjects were definitely obese, but did not necessarily present themselves for examination from this point of

view; every case of obesity in which a glucose-tolerance curve was made during the last fifteen years has been included. No examples of gross endocrine disturbance, with the exception of diabetes, are given in this paper. It is possible that the series does not represent a fair sample of the obese population of the country, as the cases have, in the main, been derived from the better-off classes. A small proportion only have presented themselves because sugar has been found in the urine.

In discussing the question of obesity it is important to have some standard of normality from which to work. So far as it has been possible to ascertain, no such standard is available. One is therefore compelled to fall back on the weight tables published in the textbooks. These tables are not really tables of "normality," but have been compiled from people, apparently in good health, presenting themselves for insurance. The weight tables therefore express an average weight but not an index of normality. It is probable that the greater the age of the subject the greater the error. For example, a six-foot man at the age of 25 has an average weight of 11 st. 3 lb., while at the age of 42 a weight of 12 st. 3 lb. is given. There is thus a gain of one stone in under twenty years. This gain might be attributable in part to increased calcium in the bones, but could not be entirely due to this. It is likely there would be a loss of weight in the musculature with advancing years which would, to a large extent, set off the increase. It is hard to see how this increase can be explained except by the

increase in fat laid down as life advances. There would appear to be little real reason for a normal person to increase more than a few pounds in twenty years. The same argument can be brought forward in the woman.

There would seem to be the same fallacy in the textbooks with regard to blood pressures—a rise here as age advances is looked upon as normal, whereas it is really an average, and is in any case a degenerative condition. In the absence of normal weight tables the average weight tables have been employed here.

Technique of the Tests

The glucose-tolerance curves have all been arrived at by the method of Hagedorn and Jensen. A standard technique has been adhered to for obtaining the glucose tolerance throughout the whole period of fifteen years. The patients are encouraged to follow their usual unrestricted dietary regime until the night before the test is made. On the morning of the test a standard breakfast is given at 8 a.m.: one cup of tea with milk, with one lump of sugar if usually taken; one slice (about 1 oz.) of bread or toast, and butter. The glucose-tolerance test begins at 10 a.m.; 50 grammes of glucose in 300 c.cm. of water are given directly the initial sample of blood has been taken. Urine is collected at the start, and at one hour and two and a half hours after the glucose.

Analysis of Results

The curves obtained (Fig. 1) have been somewhat arbitrarily grouped under six headings, and are conventionally recorded in this table.

TABLE I

- Curve No. I.—A normal rise not above 180 mg. at the half hour and thenceforward a normal descent to below 120 mg. in the one and a half hours.
- Curve No. II.—A rise not above 180 mg., but a slow descent not reaching 120 mg. in the one and a half hours.
- Curve No. III.—A flat curve under 135 mg. throughout the two-and-a-half-hour period.
- Curve No. IV.—A peak at the half hour above the 180 mg. line, but a return to the 120 mg. line or below at the one-and-a-half-hour period.
- Curve No. V.—A peak at the half hour or one hour above the 180 mg. line, and failing to reach the 120 mg. line until the two-hour period.
- Curve No. VI.—A "diabetic curve": a considerable elevation above the 180 mg. line, 120 mg. not being reached at the two-hour period. This curve has been called "diabetic," but it does not mean to indicate that the author considers that a curve of this type is definitive of the clinical condition diabetes mellitus.

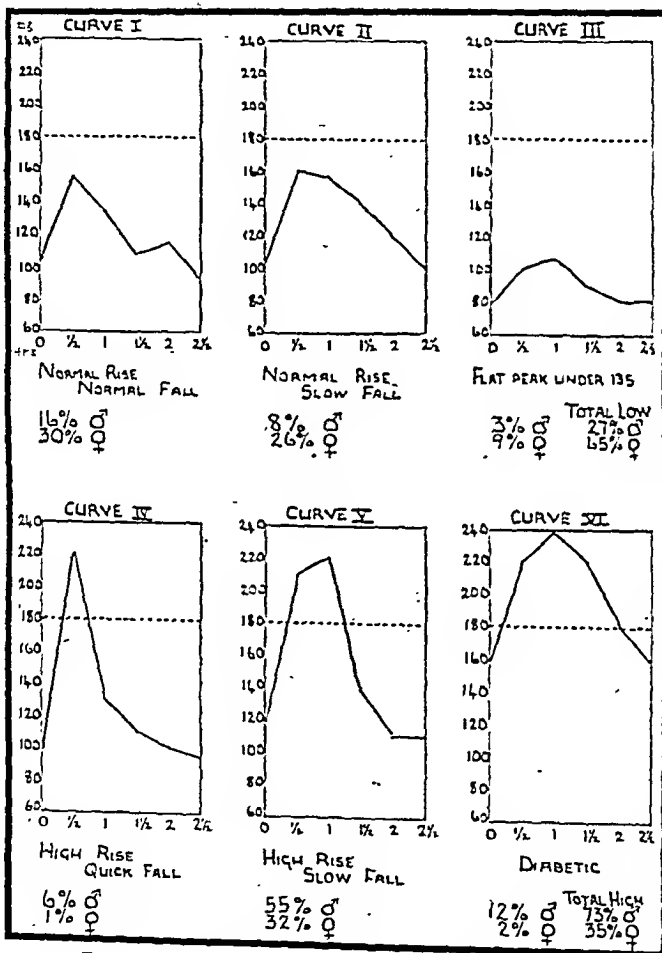

FIG. 1.—Glucose tolerance curves obtained in 500 obese cases.

* Read in the Section of Pathology at the Annual Meeting of the British Medical Association, Plymouth, 1938.

The most striking result from the analysis is the difference between the obese of the two sexes. The males show a total of 73 per cent. high curves for all ages, whereas the females show only 35 per cent. of high curves. This difference in response to glucose is still more pronounced if the percentage of high curves is plotted for

FIG. 2.—Percentages of obese cases showing high glucose-tolerance curves at various age groups.

the various decades, as in Fig. 2. Here we see that in the male up to the age of 35 years the percentage of high glucose-tolerance curves is below 30. After this age a sudden rise occurs, so that between 35 and 45 nearly 80 per cent. of obese males show a high glucose-tolerance curve, after which this high level is maintained up to the age of 65 and beyond. Obese women, on the other hand, show a very different picture. The percentage of high curves remains low until a decade later—45 years. The rise when it occurs is less sharp, the highest percentage of high curves (70) not being reached until the decade 55 to 65 years. From this it would appear that the condition underlying the obese state is different in the two sexes, or, what is more likely, a smaller number of women suffer from the defect commonest in men.

A striking difference is often evident in the post-mortem room. An obviously obese woman may be encased in layers of fat, but within this the body appears healthy and the muscles a bright red and not infiltrated with fat. In the male this is very rare, if it ever occurs, the musculature being heavily infiltrated with fat. With regard to the obese males showing normal or low curves, no distinct type could be picked out, but an analysis gives the following peculiarities:

| | |
|---|-----|
| Renal glycosurias | 34% |
| Thick-set; barrel-shaped chest, short thick muscular limbs; athletic, intelligent | 30% |
| Impotence; sex organ defects | 6% |
| Patients already on diets—namely, gastric and duodenal cases | 18% |

In Table II an analysis of these obese subjects is shown, in which the percentage of high blood-sugar curves is correlated with percentage of overweight. The figures for the males are not very regular, but it would not appear that a male is more likely to have a high blood-sugar curve if he is 50 per cent. overweight than if he is even more regular, with the exception of the first and last in the series, but give the same result. A woman 60 per cent. overweight is not more likely to show a high blood-sugar curve than one only 10 per cent. overweight.

TABLE II.—An Analysis of the Cases

| Percentage Overweight | Percentage High Glucose-Tolerance Curves | |
|-----------------------|--|---------|
| | Males | Females |
| Under 10 | 67 | 50 |
| 10 - 20 | 78 | 33 |
| 20 - 30 | 60 | 29 |
| 30 - 40 | 79 | 35 |
| 40 - 50 | 67 | 30 |
| 50 - 60 | 100* | 33 |
| Over 60 | 100* | 57* |

* Too few cases for accuracy.

Summary

In an analysis of 500 obese subjects (242 males, 258 females) it has been shown:

1. That high glucose-tolerance curves are obtained in 73 per cent. of males but in only 35 per cent. of females.
2. That up to the age of 35 high glucose-tolerance curves occur in only about 27 per cent. of males and 23 per cent. of females. Above this age about 80 per cent. of obese males have a high curve; but women always show a much lower percentage, only reaching a maximum of nearly 70 per cent. at the 55-65 age period.
3. That the percentage of high glucose-tolerance curves does not increase *pari passu* with an increase in the subjects' weight.

CORNEAL TRANSPLANTATION RESULTS OF A SERIES OF 56 OPERATIONS ON 48 EYES*

BY

J. W. TUDOR THOMAS, D.Sc., M.D., M.S.,
F.R.C.S.

Honorary Ophthalmic Surgeon, Cardiff Royal Infirmary;
Associate Surgeon in Charge of the Corneo-plastic
Department of the Central London Ophthalmic
Hospital

At the B.M.A. Annual Meeting held at Oxford in 1936 I read a paper on the results of corneal transplantation, including some references to those obtained by other surgeons (Thomas, 1937). In the present paper my own results will be given and classified, but space will not permit me to enumerate those of others. It is gratifying, however, to know that excellent results are now being obtained by many surgeons in all parts of the world. The technique I employ is similar to that which gave me the best results in experimental rabbits (Thomas, 1931) and was afterwards used for operations on man (Thomas, 1935); but since the 1936 paper it has been modified in two ways—namely, by using saline instead of oil for receiving the graft, and by so arranging the cross-stitches that the knots do not lie on the graft or on its margin. These modifications were described at the Oxford Ophthalmological Congress in 1937 (Thomas, 1938), and their adoption appears to be justified by the results obtained since 1936.

The results of all my corneal graft operations from the first one in 1930, nearly eight years ago, to the fifty-seventh operation, four months ago, are here given. The scheme described in 1936 (Thomas, 1937) is again adopted for the classification of eyes as "suitable" or "unsuitable".

* Read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Plymouth, 1937.

and for the tabulating of the results obtained. It is to be emphasized that the result is to be judged by the clarity of the graft, taking into account any membrane that may have formed on its posterior surface. Thus one might have a clear graft on an amblyopic eye which only sees fingers at one foot, the result being classified according to the clarity of the graft rather than the vision obtained. This actually happened in one of my cases, where the operation was performed in the knowledge that the eye was probably amblyopic.

TABLE I.—Classification of Fifty-six Operations on Forty-eight Eyes

| | Operations | Eyes |
|--|------------|------|
| Group A.—Suitable eyes in favourable patients .. | 26 | 23 |
| B. " " " unfavourable " " .. | 5 | 5 |
| C.—Unfavourable eyes, due to: | | |
| (a) extra-ocular conditions | 10 | 7 |
| (b) Intra-ocular conditions | 14 | 12 |
| (c) Extra-ocular and intra-ocular conditions .. | 1 | 1 |
| | 25 | 20 |

TABLE II.—General Results of Fifty-six Operations on Forty-eight Eyes

| | 56 Operations | 48 Eyes |
|--|---------------|------------|
| Successes { | | |
| Group 1: Clinically transparent | 8 | 8 |
| " 2: Slight opacity | 15 | 14 |
| " 3: Much opacity but less than original opacity | 12 | 10 |
| | 35 (62.5%) | 32 (66.7%) |
| Failures { | | |
| " 4: Opacity equal to or worse than before | 19 | 14 |
| " 5: Graft detached | 1 | 1 |
| " 6: Eye lost | 1 | 1 |

For the whole series successful results were obtained in 62.5 per cent. of the operations and 66.6 per cent. of the eyes.

| Explosions .. | 3 | 1 | 0 | 0 | 2 | 0 |
| Ophthalmia neonatorum .. | 5 | 1 | 1 | 0 | 3 | 0 |
| Iridocyclitis and sclerosing keratitis | 3 | 1 | 0 | 0 | 2 | 0 |

The results obtained in the nine eyes with interstitial keratitis were: Group 1 five, Group 2 one, Group 3 three, so that all nine cases were successes. The groups of chemical burns and measles and ulcers each showed nine successes out of fourteen.

TABLE IV.—Results of Twenty-six Operations on Twenty-three Eyes in Group A (Suitable Eyes in Favourable Patients)

| | 26 Operations | 23 Eyes |
|-----------------|---------------|------------|
| Successes { | | |
| Group 1 | 8 | 8 |
| " 2 | 9 | 8 |
| " 3 | 7 | 6 |
| | 24 (92.37%) | 22 (95.6%) |
| Failures { | | |
| " 4 | 2 | 1 |
| " 5 | 0 | 0 |
| " 6 | 0 | 0 |

The results of Group B showed one success out of five

The results of Group C(a) (extra-ocular unfavourable conditions) showed four successes out of seven, while those of Group C(b) (intra-ocular unfavourable conditions) showed four successes out of twelve. The one case in Group C(c) was successful (Result Group 3); this case was particularly gratifying, because the patient has obtained enough vision to see to move about and look after himself, in spite of the fact that his eye before grafting showed considerable adhesion of the iris to the cornea and bands of scar tissue passing from the conjunctiva on to the cornea, and was regarded as very unfavourable for operation. The operation, however, has been amply justified by the modest result obtained.

TABLE V.—Results of Grafts since 1936 (Modified Technique): Twenty Operations on Sixteen Eyes

| Results of Operations | Suitability Group | | | | |
|-----------------------|-------------------|---|------|------|------|
| | A | B | C(a) | C(b) | C(c) |
| Group 1 | 4 | 0 | 0 | 0 | 0 |
| " 2 | 3 | 0 | 2 | 3 | 0 |
| " 3 | 2 | 0 | 1 | 0 | 1 |
| " 4 | 0 | 0 | 0 | 4 | 0 |
| " 5 | 0 | 0 | 0 | 0 | 0 |
| " 6 | 0 | 0 | 0 | 0 | 0 |

TABLE VI.—Summary of Results of Twenty Operations on Sixteen Eyes

| Results | 20 Operations | 16 Eyes |
|---------------|---------------|---------|
| Group 1 | 4 | 4 |
| " 2 | 8 | 8 |
| " 3 | 4 | 2 |
| " 4 | 4 | 2 |
| " 5 | 0 | 0 |
| " 6 | 0 | 0 |

Successes in Group 1—that is, clinically transparent grafts—amounted to 20 per cent. of the operations and 25 per cent. of the eyes, compared with just over 13 per cent. and 15 per cent. respectively for the thirty-six operations on thirty-two eyes reported in the 1936 paper. The successes for Groups 1, 2, and 3 since 1936 are 80 per cent. of the operations and 87.5 per cent. of the eyes, compared with just over 58 per cent. and 65 per cent. respectively in the 1936 paper. These figures show improved results by the modifications in technique adopted in 1936.

TABLE VII.—Results of Four Eyes Regrafted Since 1936

| Suitability Group | No. of cases | Result Grouping | |
|-------------------|--------------|-------------------|------------------|
| | | Before Regrafting | After Regrafting |
| A | 1 | 3 | 2 |
| C(a) | 1 | 4 | 2 |
| C(b) | 2 | 3 | 2 |
| | | 4 | 4 |

The results of these four cases therefore show improvement in three and no alteration in one. Before the 1936 paper four cases—two in Group A and two in Group C(a)—were regrafted, the results showing no improvement in any of them. These facts lend support to the

view that the modifications in treatment since 1936 have increased the chances of success both in suitable and in unfavourable eyes.

Maintenance of Improvement after Corneal Grafting

Perhaps one can best obtain the facts necessary to estimate the chances of maintaining the results of corneal grafting by considering the thirty-two eyes operated on up to 1936 and then reported. The patients were operated on in the period between seven and a half and two years ago. Two died before 1936, and in the case of the remaining thirty, seven grafts are now classified under a new result grouping. Three out of four eyes (Suitability Group A) show deterioration to a lower result group: one from Result Group 1 to Group 2 and two from Group 2 to Group 3. The fourth eye showed improvement from Group 3 to Group 2. Three eyes (Suitability Group B) showed deterioration: one from Result Group 2 to Group 4, one from Group 3 to Group 4, and one from Group 4 to Group 6.

These figures show that out of thirty grafts one improved and six deteriorated, while twenty-three remained as before over a period of some years. Seventeen of the thirty grafts were recorded as successes in 1936, and now, after a period of years, 14 are still so recorded. It is of interest to note that the patient whose graft improved was a case of interstitial keratitis, and the patient whose eye had to be removed owing to ulceration, a long time after the graft operation, was a very intractable young child who was able to give her eye very little fair treatment. One of the patients whose graft deteriorated from Result Group 2 to Result Group 3 is well known to our president, Sir Stewart Duke-Elder, and there were perhaps a few special reasons to account for the deterioration, such as chronic conjunctivitis and a tendency to recurring ulceration. There was also the common factor in these cases done before 1936 that oil was used for the reception of the graft, and probably it contributed to the deterioration in this patient's graft. The eye was regrafted six months ago, and the result grouping has thereby been raised from Group 3 to Group 2.

Summary

In the whole series of cases 62.5 per cent. of the operations and 66.6 per cent. of the eyes operated on were successes. The nine cases of interstitial keratitis were all successes, five of them exhibiting grafts that were clinically transparent. Operations on favourable cases showed 92 per cent. successful.

The results of cases operated on since 1936 by the modified technique show 80 per cent. of the operations successful, while the nine classified as favourable cases were all successful, and four of them had clinically transparent grafts.

The latter group of figures show improvement on the 1936 results, as do the results of the four regrafting operations, three of them being beneficial. While it is a fact that some grafts will fail to maintain the initial degree of transparency, this paper shows that in a series of thirty corneal grafts observed over a period of years one actually improved and six deteriorated. Three of these were in favourable cases, and although they deteriorated were still successful. The other three were in unfavourable cases. It is anticipated that with the modified technique now used the deterioration of 20 per cent. of the grafts over a period of years will be con-

siderably reduced. At any rate, of those done before 1936 80 per cent. maintained their improvement.

In conclusion it is of interest to note that my best visual result is 6/9, and there are others with 6/12 vision, so that it is quite possible to obtain practically normal vision after corneal transplantation. One of my patients recently read four novels in ten days while on a voyage—two years after her operation.

VITAMIN C IN THE TREATMENT OF WHOOPING-COUGH

BY

DOUGLAS GAIRDNER, B.M., B.Ch.

Out-patient Medical Officer, the Hospital for Sick Children,
Great Ormond Street

The introduction of an effective treatment for whooping-cough is a matter of no little importance, since this disease now causes more deaths in this country than does any other infectious fever (Harries, 1938).

It seems true to say that although "nearly every newly discovered remedy in ancient and modern times has at one time been advocated for treatment of this disease" (Abt, 1937), there is not one that has been proved to have an appreciable effect on its course. Of vaccine or endotoxin therapy, lately so enthusiastically recommended, the conclusion of such an authority as Harries "that the more carefully the results are controlled the less impressive do they become" seems inescapable in the light of recent reports (Begg and Coveney, 1936; A. R. Thompson, 1937).

Earlier Experiences with Ascorbic Acid

The use of vitamin C or ascorbic acid as a remedy for whooping-cough was first reported by Otani (1936) from Tokyo. He found that ascorbic acid when added to a solid medium on which *H. pertussis* was grown inhibited the growth of that organism. The organism so cultured had impaired virulence when injected into rabbits (Apparently these results were not controlled by substituting for ascorbic acid some other substance having a similar powerful reducing action.) Grooten and Bezssonoff (1936) also found that ascorbic acid in concentrations as small as 0.008 per cent. inhibited the growth of *H. pertussis* in culture media, whereas it had no such effect upon other organisms at concentrations up to 0.5 per cent. Acetic acid in similar amounts was found to be inert. Otani also found that in the presence of ascorbic acid the intradermal injection of *H. pertussis* toxin produced a diminished reaction in the rabbit: the effect was noted either when the ascorbic acid was mixed with the toxin or when the animal received a previous large dose of the acid. From these experiments Otani concluded that ascorbic acid specifically antagonizes the growth of *H. pertussis* and also inactivates its toxin. Scant details are given of the results of treatment of eighty-one patients with whooping-cough who were given intravenous or intramuscular injections of 50 to 200 mg. of ascorbic acid every two to three days; sixty-six of these were thought to be improved and fifteen unaffected. Results were better when treatment was started within the first week of the paroxysmal stage.

Ormerod and UnKauf (1937) of Winnipeg independently reported favourable results with ascorbic acid. They showed that "unsaturation" with ascorbic acid was common in cases of whooping-cough, a fact which was suggested also by the observation of Woringer and Sala (1928) of four cases of scurvy developing in the course of the disease. Using the urinary excretion method of assessing ascorbic acid saturation they worked out a standard dosage sufficient to saturate every case within a few days, irrespective of age or weight, and to maintain saturation throughout the course of the disease. Twenty-seven patients so treated were described: twenty-two were children whose symptoms had been present less than three weeks—that is, cases comparable with my series. The average duration of symptoms was nine days before and a further fourteen days after treatment was started, giving twenty-three days as the average course of the disease—a figure which is decidedly below that usually found in this country. There were no controls in this series.

The Present Series

This communication gives the result of treatment of forty-one children with whooping-cough, twenty-one of whom were treated solely with large doses of vitamin C, and twenty served as controls. They were seen as out-patients once a week; they became "treated" or "control" cases according to the day of the week on which they were first seen. Only those cases are included in this series which satisfied one or more (in the majority at least two) of the following diagnostic criteria:

1. *H. pertussis* recovered from cough plate.
2. A typical paroxysmal cough witnessed.
3. A suggestive history combined with the presence of either a sublingual ulcer or a marked lymphocytosis.

Only those whose cough was of less than three weeks' duration when first seen are included. The mothers were asked to note down on a form the number of paroxysms occurring during each separate day and each night, thus making the assessment of progress and of cure as objective as possible. In this way there was little need to rely on the parents' impressions as to whether the child was better or not. When the night cough had entirely ceased and the day cough was either absent or, if present, was stated to be quite slight and lacking a paroxysmal character, the patient was discharged. Each child was also weighed weekly, for in a disease where vomiting and loss of appetite are often prominent symptoms the child's weight chart was found to be a valuable guide to progress.

The Dosage Used

Conditions precluded any urinary or other estimations; therefore the policy was adopted of giving each "treated" child very large doses of vitamin C. The results of Ormerod and UnKauf were utilized when deciding on a standard dosage which was sufficient to ensure the rapid attainment and maintenance of "saturation." The dosage adopted was: first week, 200 mg. daily; second week, 150 mg. daily; third and subsequent weeks, 100 mg. daily, given in divided doses. This dosage was independent of age or weight except that patients under 1 year were given half these amounts. (These doses compare with 25 mg., the approximate daily requirements of the normal child.) The total weekly dosage is almost the same as that found necessary by Ormerod and UnKauf to ensure "saturation," and is considerably more than

that employed by Otani. The form of ascorbic acid generally used was "ceetamin," a concentrate from natural sources; this was preferred to the synthetic product in view of the possibility that the latter is not identical in action with the naturally occurring vitamin (Elmby and Warburg, 1937). A few of the younger children received the synthetic acid (redoxon) as its smaller bulk was occasionally an advantage.

The controls were given cod-liver oil (15 per cent.) in malt in doses up to 1½ oz. daily, depending on age; and a mixture containing belladonna and bromide—drugs which are generally admitted to be without effect upon the duration of the disease (T. Thompson, 1929).

Results

The comparative results were as follows:

| | "Treated" | Controls |
|---|--------------|-------------|
| Number of cases | 21 | 20 |
| Average age | 2 yrs 11 mos | 3 yrs 4 mos |
| Average duration of symptoms before treatment | 10 days | 14 days |
| Average duration of symptoms after treatment | 25 " | 27 " |
| Average total duration of illness | 35 " | 41 " |
| Average total weight gained during treatment | 0.79 lb | 0.74 lb |
| Average weight gained per week during treatment | 0.22 lb | 0.20 lb |

The number of cases which were lost sight of before they had been discharged amounted to about 20 per cent. of the total, but as there was no appreciable difference between the number or type of cases lost from the "treated" and from the control series, it is considered legitimate to ignore this factor.

Complications.—The apparent incidence of complications is valueless where every case is not followed up, for it is just those cases which develop complications that may fail to report. Of the two cases of bronchopneumonia which are known to have occurred one was in the "treated" series (where it proved fatal) and one in the control series. These two cases are not included in the above results.

Summary and Conclusions

Twenty-one cases of whooping-cough have been treated with large doses of vitamin C. The illness lasted an average of thirty-five days, compared with forty-one days in twenty control cases, a difference which lies within the limits of statistical error.

The average rate of weight gained was practically the same in both the "treated" and the control cases.

These figures are in keeping with the general clinical impression that there was no striking difference in the course of the disease in the two sets of cases, and the assertion of Ormerod and UnKauf that the paroxysmal period of the disease is shortened "from a matter of weeks to a matter of days" was not confirmed.

In comparing these results with those of Ormerod and UnKauf it is seen that the average course of the disease in the cases treated with vitamin C was thirty-five days in the present series as compared with only twenty-three days in the Canadian series. The two sets of cases appear to be comparable in so far as the average period for which symptoms had existed before treatment was prac-

tically the same in both series. As there were no controls in the Canadian series, however, it is impossible to judge whether the natural course of the untreated disease varies in the two countries, or whether the considerable difference in the course of the disease in the present and in the Canadian series is due, for instance, to the application of a more rigorous standard of cure in the former series.

It is considered that the statement that the administration of vitamin C in whooping-cough has an effect upon the course of the disease is at present unproven.

My thanks are due to Dr. Donald Paterson for permission to publish these results relating to patients under his care and for his enthusiastic encouragement, to Dr. D. N. Nabarro for the haematological work, and to Dr. D. B. Bradshaw for the bacteriological work. Generous supplies of vitamin C preparations were given by Messrs. C. L. Bencard and by Messrs. Roche Products Limited.

Clinical Memoranda

Recent Experience in Typhoid Fever

The following notes may prove interesting in connexion with the leading article in the *Journal* of May 21, and the papers by Fenton, Hay, and Felix in the same issue. An aberrant case of typhoid fever occurred in a small boarding house.

The patient, a commercial traveller, was infected while going his rounds in the West of England. He admitted feeling out of sorts for a week before December 1, 1937, when his illness started abruptly with fever and pain in the right side. Commencing pneumonia was diagnosed, but four days later typhoid was suspected on account of abdominal symptoms, including the passage of blood per rectum. Incidentally there was a history of gastric ulcer five years previously. At this time blood culture together with examination of faeces and urine and the Widal reaction were negative, nor was there leucopenia. A blood count on December 11 showed a slight relative and absolute increase of polymorphs, but a further Widal test on the same date was now strongly positive for *B. typhosus* (*B. typhosus* H = agglutination up to 1 in 2,500, and *B. typhosus* O = agglutination up to 1 in 1,000).

The patient was admitted to hospital on December 11 and died on December 23 from toxæmia and respiratory failure. On admission he was obviously very ill. He was delirious, his tongue was very dirty, there were signs of recent epistaxis, and he had a slight cough and was passing blood per rectum. The abdomen was moderately distended, with gurgling in the right iliac fossa. The spleen was not palpable, but there was tenderness in that region. A few rose spots were present on the lower costal margins and one to the right of the umbilicus. Although he gave a history of not more than twelve days' illness he was clinically in the third week. In addition to general treatment he received intramuscular injections of Lister Institute typhoid serum of 30 c.cm. each on December 14, 15, and 16 without any apparent benefit.

While in the boarding-house the patient was nursed by the owner's wife, who also prepared food for other residents, one of whom was a baker in a large establishment. It seemed likely that some of the household would be infected, and, apart from taking the baker off his work, the problem was what other steps were indicated.

We decided, with their consent, to give each of the six persons in the house 12 c.cm. of Lister Institute serum in order to produce, if possible, some degree of temporary passive immunity. A week and also a fortnight later this was followed up with the usual doses of T.A.B. vaccine (Lister Institute) with a view to producing active and more permanent immunity. We believe that there is a real danger of "provocation typhoid" if vaccine is used alone in such circumstances, and we suggest that pre-treatment with serum is logical, and may possibly be sufficient in itself. No secondary cases occurred and no ill effects followed the inoculations. The sixth member of the household was a temporary visitor and had serum only so far as we know. Unfortunately circumstances were not favourable for subsequent blood examinations of the contacts, but one of us is able to vouch for the efficiency of the vaccine from controls taken elsewhere.

Regarding sulphonamide in enteric fever, one of us has tried this drug by the mouth in one case of typhoid and in several of paratyphoid B. In the latter it appeared to have a favourable effect, but it must be admitted that cases of this disease which come under treatment early often run a mild course. The single case of typhoid was a severe one, but recovered eventually. The drug had no effect one way or the other, and as the patient was found to be a temporary urinary carrier in convalescence and was a chronic faecal carrier on discharge, it would appear that sulphonamide has no bactericidal properties in typhoid fever.

Ether Convulsions, with Recovery

The use of evipan in ether convulsions was first described by R. F. Woolmer and one of us (S. T.) in 1936. Its value was independently discovered by J. S. Marr (1936), and one month later T. H. Chadwick (1936) reported his case. Dr. H. H. Pinkerton's recent account of the successful treatment of ether convulsions with evipan in the *Journal* (1938) prompts us to record two similar cases.

CASE RECORDS

Case 1.—A child aged 4 years was undergoing operation for double mastoid suppuration. The anaesthetic was ether chloride, followed by open ether, then by ether vaporized with oxygen. When anaesthesia had been in progress for six minutes, and as the operation on the second ear was starting, typical ether convulsions began. The convulsions were relieved by oxygen and CO₂, and the removal of the clothes. Evipan was then injected intravenously, and when 8 c.cm. had been given the convulsions ceased. So too did respiration, and after half a minute of CO₂ and artificial respiration the pulse also stopped. Coramine, 1.5 c.cm., was then injected into the heart, and within a few seconds pulsation started once more. Artificial respiration was continued, and three minutes later spontaneous respiration began. The respirations increased in volume, and the child made a complete recovery. The operation on the second ear, however, was temporarily abandoned. The theatre temperature was 80° F., and the rectal temperature, after five minutes with no clothes on, was 101.5° F. The ether contained traces of aldehyde, but no peroxide. Ten days later the second operation was performed, with the same anaesthetic, but paraldehyde glass was given beforehand. There was no recurrence of the convulsions.

Case 2.—A girl aged 11 years was undergoing operation for a typical acute appendix (temperature 102° F., pulse 140). The anaesthetic was ethyl chloride, followed by open ether and oxygen. There was no struggling during induction, and no CO₂ was given. After forty-five minutes, as the peritoneum was being closed, typical ether convulsions began. These were unrelieved by oxygen, CO₂, and chloroform. After three minutes of convulsions, evipan having been prepared, 2 c.cm. injected intravenously stopped them at once. They did not recur, and the patient made a complete recovery.

In the first case an overdose of evipan was undoubtedly given, probably because the injection was continued steadily until the convulsions ceased. Had 2 or 3 c.cm. only been injected and a short time allowed for this amount to circulate, it would almost certainly have been enough. We suggest that when 2 or 3 c.cm. have been given the anaesthetist should pause for at least one minute, and only inject more if at the end of that time convulsions have not stopped.

AETIOLOGICAL FACTORS

We venture to offer the following diagram, summarizing the known aetiological factors in ether convulsions and providing a provisional theory of their cause. It is rare for all the aetiological factors to be present in one case.

It is well known that ether convulsions are prone to occur in acute septic cases (see the above diagram), and we wish to draw attention to a paper by Rosenow and Tovell (1936). These workers took nasal swabs from patients during ether convulsions, and from them grew streptococci. These were injected into rabbits, which, when anaesthetized with ether, in their turn developed convulsions. Nasal swabs from the same patients, taken some days later, gave a growth of the same streptococci, but this time the injected rabbits failed to convulse under ether. They suggest, therefore, that a streptococcal nasal infection plays some part in the production of ether convulsions. This work appears to have been done very carefully, and we feel that it is worthy of repetition whenever the opportunity occurs.

In spite of the efficacy of evipan as an anti-convulsant we think that the best "cure" for ether convulsions is their prevention. We suggest, therefore, that when acute sepsis in a child or young adult demands surgical intervention, open ether is not the anaesthetic of choice. It would be safer to rely on gas and oxygen with a minimum of ether or, better still, cyclopropane if a general anaesthetic is considered necessary.

Reviews

DEFICIENCY OF VITAMIN A AND OF VITAMIN E

On Deficiency of A-Vitamin and Visual Dysadaptation. II. By C. Edmund and Sv. Clemmensen. (Pp. 52; 5 figures, 7 tables, 3s. 6d. net.) Copenhagen: Levin and Munksgaard. London: Humphrey Milford, 1937.

Effect of Chronic Vitamin E Deficiency on the Nervous System and the Skeletal Musculature in Adult Rats: A Neurotropic Factor in Wheat Germ Oil. By Larus Einarson, M.D., and Axel Ringsted, M.D. (Pp. 163; 95 figures, 2 plates, 12s. 6d. net.) Copenhagen: Levin and Munksgaard. London: Humphrey Milford, 1938.

The first of these two volumes is a report of recent investigations by Drs. Edmund and Clemmensen into the relation between vitamin A deficiency and visual dysadaptation. The subjects were pregnant medical patients, patients examined before and after administration of carotin oil, hospital nurses and male hospital attendants who receive a comparatively good diet. The authors confirmed their previous estimate of the "normal" power of distinction, and, taking this as the standard, they found that only fifty-two of their medical patients in the spring showed dysadaptation. There was a certain amount of seasonal variation in the subjects who received a comparatively good diet. These later findings were decidedly lower than those previously reported, and the authors conclude that this may be accounted for by the recent agitation in Denmark for diets rich in vitamins, and particularly by the inclusion of vitamin concentrates in margarine. Intramuscular injections of carotin oil were slow in acting, taking twelve to forty-eight hours to show any effect, whereas similar injections of vitamin A from liver oils brought about an effect in two minutes and oral administration in less than twelve hours. An investigation of the diet of a certain prison indicated that each prisoner received about 1,225 international units of vitamin A per day. These prisoners showed seasonal variation in their power of distinction. Others who received an additional 150 units per day in the form of fresh milk did not show the seasonal variations. Hence an allowance of 1,370 international units of vitamin A per day was considered to be necessary for an adult. It is a useful attempt to determine by the aid of experiment how much vitamin A is required by a healthy adult. Previous estimates of the adult's need have mostly been made by the examination of "typical diets" of apparently healthy human beings.

Drs. Einarson and Ringsted have reinvestigated the findings of one of them (1935) that adult rats fed on a vitamin-E-free diet for a long time exhibited certain neurological disturbances. Until they can use vitamin E in a pure form the authors will not claim to have proved that these disturbances are due to vitamin-E deficiency, but vitamin E and the neurotropic factor have so many similar biological and chemical properties that they conclude that the condition noted in the rats is indeed caused by a lack of vitamin E. Full details of the feeding and care of the animals are given. It was found that the neurotropic factor present in wheat-germ oil was stored in the organism in depots and withdrawn relatively slowly. Paresis appeared in the rats after feeding on the vitamin E diet for a few weeks. If treatment with wheat-germ oil was begun within the first six weeks of this special feeding, paresis did not develop; but if treatment was begun after eight weeks of this feeding paresis appeared six to eight weeks later. Wheat-germ oil

could not cure the paretic condition, but it could prevent its further development. The development of paresis is gradual; the hind legs show a pronounced straddling in walking, there is distinct atrophy of the musculature of the hind quarters and lower extremities, but the forelegs are normal. Later the hind legs are kept greatly abducted, and finally the rats are quite unable to walk about, but may drag themselves forwards with the forelegs. Death does not result even after twenty to twenty-four months of this condition. A very detailed account is given of the methods adopted for the histological examination of the tissues. There are ninety-five figures in the text and two plates, all well reproduced. The detailed descriptions of these are given in the text. The authors deal fully with the normal anatomical conditions and with the structures as influenced by the dietary deficiency. There is a full discussion of the possible (or impossible) relation of these conditions and those of animals depleted of other vitamins—A, B₁, or B₂.

A FRENCH TREATISE ON PSYCHIATRY

Psychiatrie Médicale, Physiologique et Expérimentale. By H. Baruk. (Pp. 828; 125 figures. 220 fr.) Paris: Masson et Cie. 1938.

This large treatise on psychiatry by one of the foremost French psychiatrists is welcome as an exposition of modern work in that country. The first part is concerned with a discussion of the anatomical-clinical approach which tends to seek localizations for various lesions and syndromes. While this may be more or less profitable in neurology, in psychiatry there is a tendency for those who adopt this approach to forget the fact that in its higher functions the cortex, and indeed the brain, tends to work as a whole. To illustrate this Dr. Baruk refers at length to his own work on the psychomotor syndrome of catatonia. However produced—in the course of schizophrenia, as a result of toxæmia, or by the administration of bulbo-capnine—it must be a diffuse cerebral lesion, since it is associated with deliria, with inhibition of the will, and disturbances of all sorts of psychic as well as motor functions. It is, in fact, a suspension of initiative. Using the same methods the author discusses hysteria, and believes that this is due to certain analogous physiological disturbances less profound, and therefore more readily reversible, than those found in catatonia. In the light of these ideas the duality of organic and non-organic syndromes may be resolved, the organic series being represented by changes which are more localized and irreversible, and non-organic or functional syndromes by those which are more diffuse and more superficial.

In the second part the author discusses psychiatric diagnosis and classification, and deprecates the insistence on hard-and-fast nosological entities such as those suggested by Kraepelin; he would prefer to talk of simple reactions to different aetiological factors. These reactions differ according to the localization and intensity of the neurological dysfunction. On this basis the author formulates a classification arranged in accordance with disturbed function. This point of view helps to explain the remarkable variations met with in many psychoses, their remissions, relapses, and spontaneous cures, etc.

The third part deals with treatment and management. Dr. Baruk again protests against rigidity in diagnosis and against absolutism in prognosis, which paralyzes efforts at treatment. He lays special stress on a thorough investigation of the psychological background of each patient and all the possible aetiological accidents to which he has been exposed, and considers that such investigation will demonstrate opportunities for therapeutic intervention.

Finally, he discusses certain imperfections in the French law of 1838 dealing with the treatment of mental patients, and gives his notions of the proper organization of psychiatric treatment, in which one of the most important factors is the correct "moral atmosphere."

The book is illustrated by numerous tables, curves, and statistical data, and is furnished with a comprehensive bibliography. It is certainly deserving of close study by British psychiatrists, who cannot afford to neglect the ideas of their Continental colleagues.

DUKE-ELDER'S "OPHTHALMOLOGY"

Textbook of Ophthalmology. Volume I. The Development, Form, and Function of the Visual Apparatus. By Sir W. Stewart Duke-Elder, M.A., D.Sc., St. And., Ph.D., Lond., M.D., Ch.B., F.R.C.S. Second Impression, with Corrections and Additions. (Pp. 1136; 1022 figures, including 7 coloured plates. 63s. net.) London: Henry Kimpton. 1938.

In our review of the first volume of Sir Stewart Duke-Elder's *Textbook of Ophthalmology* (July 23, 1932, p. 149) we recorded high appreciation of the work in words that we cannot do better than repeat: "This first volume is in our judgment a great book. It is great by reason of its bulk, for it exceeds a thousand pages; it is great in its conception, and also great in its achievement. The author may well be congratulated upon such a piece of work—upon his ability to produce it and his industry in producing it. Whichever way this book is examined its high standard is confirmed."

It must be a source of gratification both to the author and to the publisher that after so short a time a second edition of this work has been called for. Such a fact confirms the widespread recognition of its value to all English-speaking ophthalmologists. In his new preface the author states that advantage has been taken of the reprinting to correct and make additions to the first edition. In certain sections fundamental advances in knowledge have rendered the original text misleading, such as those relating to ocular pigment and the neurogenic origin of pigmented tumours, the biochemistry of the eye, the nature of the intra-ocular fluids, the physicochemistry of the vitreous body, and the chemical and electrical reactions in the retina. We wish this new impression as complete a success as the first.

FITNESS AND NUTRITION

The Wheel of Health. By G. T. Wrench, M.D. Lond. (Pp. 146; frontispiece. 6s. net.) London: C. W. Daniel Co. Ltd. 1938.

The relation of nutrition to physical fitness and the maintenance of health is to-day receiving much emphasis. Indeed, perhaps one of the most remarkable features of recent progress in medical science is the recognition that many pathological conditions, whose origin had previously been obscure, are primarily the result of nutritional defects. In his book *The Wheel of Health* Dr. Wrench has given expression to this reorientation of views in regard to the causation of disease which is also being experienced by many of his fellow-workers. The author takes as the text of his essay the Hunza people of Northern India. These people are relatively secluded in the fertile Hunza valley, and have impressed many observers with their fine physique and their comparative immunity from many of the diseases which affect their neighbours. They are capable of almost incredible feats of physical endurance, and obviously provide an excellent opportunity for the study of those conditions of life which allow the most perfect development of human physique and the maintenance of

bodily health. From a consideration of the Hunza people Dr. Wrench passes on to a brief review of the classical studies of Sir Robert McCarrison, studies which may rightly be regarded as the starting-point for the inquiries into the relation of diet to health which have been carried on since with increasing intensity. Reference is also made to the diet and health of other races of mankind, to the observations on the health of the Danish population during the late war when rationing had to be extensively controlled, and to the work of McGonigle and others in this country.

The evidence which the author collates in support of the primary function of effective nutrition in the maintenance of health is very impressive. He concludes, indeed, that "disease is the censor pointing out the humans, animals, and plants who are imperfectly nourished." If at times he lays himself open to the criticism of over-emphasis on nutritional factors, there are many who would agree to-day that this is an excusable fault. His case is so strong, however, that it in no way lessens the importance of his argument to suggest that what is most required now is to differentiate possible genetic factors which may complicate nutritional problems. It is well known that different individuals show a different susceptibility to dietetic defects, and recently in the laboratory a Mendelian variety of rats has been obtained which succumb to rickets when the vitamin content of the diet is lowered more readily than normal rats. How far can such genetic factors account for differences in physique in different groups of mankind? Dr. Wrench lays considerable stress on the physique and health of the Hunza people, but he also states that these people are "unique in racial characteristics." Hence, to the reader it seems at least possible that genetic racial factors may be contributory to observable differences in physique.

Dr. Wrench writes in a pleasant and stimulating style. He has done good service in bringing together in this essay the results of some of the best and most illuminating studies on nutrition in man and in pointing out the importance of these researches to social problems of to-day.

W. LE G. C.

ELECTROTHERAPEUTICS

Electrotherapy and Light Therapy. By Richard Kovacs, M.D. Third edition, thoroughly revised. (Pp. 744; 307 figures; 1 coloured plate; 57 tables. 35s. net.) London: Henry Kimpton, 1938.

Dr. Kovacs has been called upon within five years to produce a third edition of his book on electrotherapeutics. This follows the lines of the previous two, with additions and fresh chapters where progress in one particular line, such as hyperpyrexia, has taken place since the last edition. The work remains an admirable textbook written in attractive style, and is really valuable to English practitioners—an exceptional merit in a book written on electrotherapeutics by an American practising physician. Indeed, it seems certain to be recognized as a standard textbook for many years to come, and will therefore pass through further editions. The present seems therefore to be an opportune moment to put forward some constructive suggestions.

The book would undoubtedly gain if it were cut down considerably; the author's desire for clarity of explanation and completeness in all techniques has made it become "almost encyclopaedic in character." Some of the illustrations serve no useful purpose; an indistinct view of the outside of Messrs. So-and-So's diathermy or short-wave apparatus teaches nothing. Every illustration in a book of this kind should impart definite information, either on

the physical side or on that of technique. In the chapter on the results of accidents during electrotherapy there should be careful and detailed suggestions for treatment, especially for diathermy burns. Dr. Kovacs emphasizes that prevention is better than cure, but even in highly skilled hands burns do occur, and help from the experience of such an expert as the author of this book would be valuable and comforting. His electromagnetic spectrum table on page 414 is good, but could be improved by making it possible for the student to appreciate more readily the relationship between Angstrom units, which he does not understand, and centimetres, which he does. On pages 493 and 494 Dr. Kovacs's references to the Finsen treatment need revision; he appears to be unaware of the great advance made in the treatment of lupus by the introduction of the Finsen-Lomholt lamp. The book remains, however, an indispensable standby for all who employ the standard currents and methods of electrotherapy and light.

Notes on Books

Though the medical profession and the public are far more conscious than they were of the nurse as a human being and a valuable member of society, few of those who have not been through the mill have much idea of the details of her daily life: of the incidents of her training or of the job for which she is trained. *Through a Ward Window* by H. L. MONTGOMERIE (Chapman and Hall, 8s. 6d.) is the work of a nurse who trained at an easily recognizable London hospital, and it is written with real humour, sympathy, and imagination in the form of letters from the heroine to her best friend. Those who deprecate the use of this device may be assured that it is very suitable to the somewhat fragmentary narrative that such a book is bound to be. The best thing in the story is the waylaying and hair-combing of the senior honorary surgeon by the probationer who mistakes him for a newly admitted patient. The reader will not only be anxious to read to the end but at the end will really know something about what life means to the probationer nurse. It can be specially recommended to girls or their parents who are anxious to know what they are in for.

British Periodicals of Medicine: a chronological list by Mr. W. R. LEFANU, Librarian of the Royal College of Surgeons of England, has appeared in two parts in the *Bulletin of the Institute of the History of Medicine*, Johns Hopkins University, and is now reprinted in book form by the Johns Hopkins Press, Baltimore, at \$1.25. Part I attempts a survey of medical periodicals issued in all British lands from the seventeenth century to the end of the nineteenth, including those which continued into the twentieth but began publication before 1900. Part II gives a list of the periodicals which began publication during the present century. At the end of each part is an alphabetical index of titles. In all there are more than 1,360 separate items, each being arranged in chronological order under its earliest year date. For every item Mr. LeFanu has tried to indicate at least one library where a copy of the journal is filed; failing this he states the source of his information. In his preface he notes the "large infant mortality" among journals devoted to medicine and its specialties.

A Textbook of Histology for Medical Students by Dr. EVELYN E. HEWER (Heinemann, 15s.) is, as the author states, primarily written for the use of medical students, and in this respect admirably fulfills its purpose. It consists of a straightforward description of the essentials of human histology, and serves as a brief but authoritative

introduction to the subject from the purely medical standpoint. Where necessary, allusions are made to the bearing that the matter under consideration has upon general pathology: for example, the repair of fractured bone or the after-effects of injury to the nerve tissues. The author has wisely refrained from entering into any controversial questions, and, while giving the usually accepted or orthodox view, refers the reader, in cases where there are differences of interpretation of microscopical appearances, to special treatises for further information. The illustrations, three hundred and forty in number, are of two types—(1) photomicrographs, showing the general structure of the tissues or organs under a low power of magnification, many of which are excellent and form a valuable record of the specimens selected, and (2) rough diagrammatic sketches indicating the principal features of the individual cell elements under high magnification. The book contains a large amount of useful information, much of which is quite recent, and it constitutes a valuable guide to the study of one of the most fundamental subjects of the medical curriculum.

The Pharmaceutical Pocket Book (thirteenth edition) is published by direction of the Council of the Pharmaceutical Society and has been prepared by the Codex Revision Committee of that society (London: The Pharmaceutical Press, 1938, 5s., postage 6d.). A considerable proportion of the volume is in the form of tables, which provide a wide variety of information of importance to pharmacists—for example, doses, B.P. formulae in Imperial system, solubilities, etc. It also contains much information of interest to medical practitioners which is not readily obtained elsewhere—for example, a dictionary of synonyms and trade names, an account of the Poisons Law and Rules. Sections of the volume deal with subjects of general physiological interest. Thus there are articles on the vitamins and on the endocrine organs; though relatively brief, these give the essential information. A high standard of accuracy is maintained throughout the volume, and it provides a surprisingly large amount of varied information for the moderate price of 5s.

Preparations and Appliances

A SIMPLE AMBULATORY METHOD OF TREATING FRACTURED CLAVICLE

Dr. MONTAGUE DIXON (Melton Mowbray) writes: The following is an account of a simple and inexpensive method of treating fractured clavicle, with apparatus that is always easily available.

Material required: novocain 2 per cent., and a 20-cm. Record syringe; zinc oxide strapping, two inches wide; some fine string; a packing needle; a three-inch elastoplast bandage; a six-inch bandage; Gamgee tissue; talc powder.

1. Inject the haematoma at the fracture with the 2 per cent. novocain solution to procure analgesia and resulting relaxation.

2. Measure the vertical sagittal circumference of the shoulder round the axilla, opposite the coracoid process. Let this measurement be called x inches. Cut four strips of the two-inch strapping $x + 6$ inches long to make two double strips of plaster, one for each of the two rings required. Each of these strips will have one surface sticky. Place them on the table sticky side uppermost. Cut four further strips, two to be four inches less than half the length of the double strips and two to be two inches less than this length. Place the longer of these, in each case, at the end of the double strip to eliminate the sticky part by putting sticky portion to sticky; and the shorter of them four inches from this longer one, to reach to two inches from the other end. The resulting strips will be threefold except where their surfaces are sticky,

uncovered by the final strips, the sticky parts being a median portion four inches long and a terminal portion two inches long, indicated by the shaded areas in Fig. 1.

Fig. 1.

3. Make two circular rings of these strips by bringing the ends together, the terminal sticky two inches being applied to the other end of the strip. This junction should be fortified by stitching the ends together by means of the fine string and the packing needle. A quadrilateral stitch, four holes being made, will suffice (Fig. 2).

Fig. 2.

4. Cut twelve pieces of the strapping, each four inches long; take six of them to make a pad for each shoulder, six layers thick, which should be placed over the coracoid tip vertically in front of the outer fragment of the clavicle, to take the pressure of the ring (Fig. 3).

Fig. 3.

Fig. 4.

5. Now place the rings over the shoulders, and pull the shoulders outwards and backwards to reduce the overlap of the fragments, fastening the rings towards each other by the six-inch bandage, which should be tied in a bow for future adjustment. The rings will have been so applied that the sticky middle portions rest upon the six-layer pads. When the rings are tied the axilla should be liberally powdered to prevent the hairs sticking and dragging; it is better to powder as soon as the sticky middle has been accurately placed and pressed down upon the protective pads; but take care that no powder interferes with the adhesion of the sticky middle of the rings to the pads. Thus the rings will never slip during the course of the treatment.

6. Place a thick pad of folded Gamgee tissue under the knotted six-inch bandage behind.

7. It only remains to defeat the downward pull of the weight of the forequarter by means of the elastoplast bandage, which should be passed from the shoulder of the sound side round the elbow, where it holds the proximal end of the ulna, and again to the sound shoulder; this should go twice round for firmness and strength. Fix the bandage at the elbow with additional strips of zinc oxide strapping at its edge (Fig. 4).

8. A narrow sling can be worn except when the hand is being used.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 8 1938

AIR RAID CASUALTIES

We as a profession, in common with the country, pray for peace in our time. But if we are to be granted no more than a respite from war we are resolved that we shall not again be caught unprepared. In particular we are concerned with the arrangements for casualties in the event of air raids on London. For some years hospitals and their staffs have asked, and asked in vain, what would be required of them in the event of war. It was therefore with a sense of relief that the profession read, early in June this year, the Home Secretary's announcement in the House of Commons that he had appointed a committee with Sir Charles Wilson as chairman to advise on the casualty organization for London. The personnel of that committee was in itself an assurance that a workable plan would be thought out without waste of time, and it is understood that the committee did present within six weeks of its appointment an interim report to the Minister of Health containing apparently the gist of the whole matter. In drawing up its report the committee received invaluable assistance from a careful survey of the available hospital accommodation in the country made by the Ministry of Health and from the census of the profession compiled by the British Medical Association. An account of the Association's part in mobilizing medical man-power for war will be found in the *Supplement* this week. The work of the head office at Tavistock Square in this connexion has been of the greatest help in shaping a plan for dealing with personnel.

The Wilson report was, we understand, accepted by the Ministry of Health, but it has never been published, and since the committee was appointed only in an advisory capacity we have no assurance that its recommendations have been carried out. We know that certain preparations have been made by London hospitals for the reception of casualties. But it is not in the hospital arrangements that a breakdown may be anticipated. The casualties have first to be removed from the streets and taken to the nearest hospital. Is there in existence an adequate body of stretcher-bearers or is it merely

a figure on paper? And have effective transport arrangements been made for taking casualties to the nearest hospital? These are the foundations of any plan, and unless they have been firmly laid the whole scheme must break down. Further, since the casualties must be removed from the danger area as soon as possible, a large number of beds in base hospitals in the home counties is necessary. Has sufficient provision been made for these outlying beds?

The advisory committee, as we have said, reported in July, and we understand that Sir Charles Wilson has paid a warm tribute to Dr. Hebb and others at the Ministry of Health who spent August and September, when others were on holiday, giving effect to the committee's recommendations. But the first secret of administration is devolution, and there is a feeling abroad that the Ministry in tackling a vast job when time was everything would have been well advised to seek more help from outside. At any rate, when the international situation deteriorated late in September the casualty organization was not ready for a war which appeared to be imminent. The hospitals were asked to prepare for the reception of casualties, and we know some of the steps that were taken in their conversion into casualty clearing stations. Some of them, such as St. Bartholomew's, St. Mary's, the Middlesex, and the London appointed a member of their staff as commandant. Preparations were rapidly made for adapting old buildings to new purposes and for the evacuation of as many of the sick as possible either to their homes or to base hospitals. But there cannot have been effective co-ordination of this effort, for when some hospitals were ready to take casualties others had scarcely begun their preparations. Moreover, the efficiency of a hospital, for whatever purpose it is used, ultimately depends on its staff, and it was everywhere found impossible to appoint a war-time staff in the absence of the necessary information about financial assistance from the central authority. The teaching hospitals, for example, cannot expect to retain their present staffs in their entirety. They will have to rely on a skeleton staff in the manner of the casualty clearing stations of the great war, the remainder of the staff being required elsewhere. In practice, some at least of this skeleton staff will probably have to devote all their time to the service of their hospital. But the hospitals are still in ignorance as to whether the State is prepared to pay salaries to these whole-time workers. Further, since the brunt of a raid may fall on some particular part of London while the rest escapes, it is necessary to organize mobile surgical teams, and so far as we know this has not yet been done.

It would not be difficult to multiply examples of the absence of adequate preparations. It is plain from the experience of the great war that medical schools ought to carry on in the event of war, but the schools do not yet know whether their students would be conscripted, if and when there is conscription. They are still in ignorance of the Government's policy, and they cannot begin to make arrangements until they know that policy. Further, when there is talk of filling the teaching hospitals entirely with casualties, they wonder how they are to train their students in the clinical years in the absence of ordinary ward material. Men returning from summer holidays report that there is scarcely a hamlet in the land without an elaborate organization for dealing with gas casualties, though the odds against a bomb, much more a gas bomb, disturbing the sylvan peace must be about one in a million. And while the depths of rural England are busy with this minute preparation, London, which must expect no such immunity, postpones the most vital preparations to the eleventh hour or later. It is idle to deny that such a lack of proportion and of horse sense is disquieting. Between two and three million civilians are to be evacuated out of London and billeted in town and village, so that in many places there will not be a vacant room. Have arrangements been made for the medical care of these refugees? Questions of that kind are on everyone's lips. Men ask, Are there enough stretchers, blankets, beds?

It is a time for plain speaking. The committee for casualty organization, announced in Parliament in June for the purpose of allaying public misgivings, and saddled in the minds of the profession with the responsibility of producing a plan which would work, was not permitted to finish its task. It has not apparently met since it presented an interim report in July. Why? If this procedure is to become the practice of Government departments difficulty will be found in persuading responsible members of the profession to come to their assistance. Out of these misgivings a moral emerges. In the great war the combatant services appointed consultants to assist in an advisory capacity. If there is unhappily to be another war London will be the front line. The arrangements for coping with casualties from air raids will concern millions of its inhabitants and a considerable fraction of the medical profession. It is unthinkable that any Government department would attempt the solution of a problem on this scale relying only on its own resources, considerable as they may be; it would certainly seek the assistance of the best brains in the medical profession. The public and the profession could be content with nothing less.

SEASONAL PERIODICITY IN MALARIA

Seasonal periodicity is a familiar phenomenon in both the vegetable and animal kingdoms. When it is remembered that the aetiological cycle of malaria involves no fewer than three animal forms—man, the mosquito, and the parasite—it is perhaps not so surprising that this disease should be almost as regular in its vernal and autumnal manifestations as the blossoming and fruiting of trees. Our knowledge of the causes of seasonal variation in malaria and the expression of this variation in an exaggerated form as epidemics is still, however, very imperfect. Explanations on accepted lines often fail to satisfy when subjected to close examination. In *The Seasonal Periodicity of Malaria and the Mechanism of the Epidemic Wave*¹ Colonel C. A. Gill deals in a very informative way with this aspect of malaria. Malaria exhibits itself under very different phases in different localities, but there is a general similarity, according to the author, in many of its features as seen in the temperate, subtropical, tropical, and equatorial zones. Thus malaria in a temperate zone represents malaria in the absence of the malignant tertian parasite and has many features due to the peculiar property of the benign tertian parasite of lying dormant and relapsing after long intervals. The spring epidemic characteristic of malaria in this zone, it is now known, takes place at a time when there are practically no anophelæ and is due to the delayed effects of infection contracted in the previous autumn. Malaria in a subtropical zone is exemplified by conditions in South Italy. There are two epidemic periods, one in the spring and another, the more important, in the autumn. The delayed primary attack of benign tertian, so conspicuous in Holland, is here less common and most of the spring cases are relapses in persons who have already suffered in the previous autumn from an actual attack of fever. Further, where the mean temperature during the hottest months is not less than 20° C. (for example, South Italy) manifestations of malignant tertian give special features to the autumnal rise. Tropical zone malaria is very similar in its general features to the last-mentioned type, but differs in the great intensity of the autumn effects as shown by morbidity and mortality and also by the fact that, whereas in subtropical zone malaria the determining factor is mainly temperature, in tropical zone malaria it is humidity (rainfall). Equatorial zone malaria, again, shows spring and autumn periodicity, but here both epidemic periods are of equal amplitude, and instead of rainfall drought is the chief determining factor. The distribution of these different epidemiological

¹ London: J. and A. Churchill. 1938. 10. 6d.

types of malaria, their distinctive characteristics, and the mechanism of the epidemics associated with them, so far as known, are clearly set out with some very good illustrative charts and a map of the world giving the limits of the zones. An extremely interesting and instructive analysis is given of the European types of seasonal prevalence which has been made possible by the very thorough researches carried out more especially in Holland and Italy. The characteristic features of the North Indian type of epidemic and the Ceylon epidemic are also closely studied. The most puzzling problem with which Colonel Gill has to deal is one that has already been prominently brought forward in discussions relating to the last-mentioned epidemic—namely, the nature of the mechanism by which malignant tertian malaria becomes so rapidly prevalent at the beginning of an epidemic. Practically all authors agree in regarding malignant tertian malaria as not exhibiting the long relapse seen in benign tertian malaria, and we have ample evidence that in the beginning of such epidemics there is very little infection in the form of gametocyte carriers to explain the remarkably rapid rise of infection with its resulting morbidity and mortality. Colonel Gill puts forward the view, for which he gives certain evidence, that the seasonal epidemic wave, even with malignant tertian, is initiated by a seasonal wave of relapses. He thus hypothesizes that there is some cause at present unknown bringing about such a seasonal wave of relapses. In a short appendix he clearly tabulates the mean monthly figures for temperature and humidity of a number of selected localities in the different malaria zones which should be very useful for reference. Even though his conclusions may not always be accepted, the very clear exposition of what is at present known regarding seasonal effects in malaria and the mechanism of epidemics makes the book one that every malariologist should read.

SUDDEN "EXHAUSTIVE" DEATH IN EXCITED PATIENTS

Shulack¹ has recently drawn attention to a problem which has puzzled psychiatrists for a long time, and has been the subject of a number of recent German publications. Young and healthy persons suddenly fall ill with a grave psychosis having as its main symptoms extreme motor excitement, aggressiveness, and a tendency to ruthless self-destruction (for example, by self-castration, bashing the head against the wall, etc.). The excitement resists all treatment by sedatives, of which only restricted use can be made because of the rapidly appearing disturbances of circulation. There is often

a short rise in temperature, and after a few days the psychosis ends fatally. The impression is often gained that the patient dies of exhaustion due to continuous struggling and excitement. The post-mortem findings offer no explanation for the malignant course, and no definite cause of death is found. Shulack collected 364 cases of this kind from the literature, adding twelve of his own. Stefan² collected 148 patients, and Stauder³ twenty-seven from the Munich Psychiatric Clinic. This, however, gives an exaggerated idea of the frequency of this syndrome: Scheidegger⁴ was only able to collect forty-three cases from the records of twenty-eight years in the Zurich Clinic. Whereas the German papers are well documented with post-mortem findings, a necropsy was carried out in only two of Shulack's cases. Examination of the histological findings in the brain is indispensable for excluding barbituric poisoning as a cause of death. All kinds of sedatives, especially scopolamine, are extensively used in severe excitement, and their combination with exhaustion, refusal of drink and food, and psychomotor excitement provides a most obvious, though as yet unsubstantiated, explanation of the fatal course. Swelling of the brain, hyperplasia of the thymus and other endocrine anomalies, and under-development of the whole circulatory system have all been found in individual cases. Jahn and Greving⁵ found erythropoiesis in the marrow of the femur and other signs of accelerated new formation of the red blood cells in five cases, and drew a parallel between these findings and the effect of histamine poisoning in animals. According to Scheid⁶ these findings also are not of general application. All ordinary physical explanations, therefore, are as yet premature; and one is faced by the question whether death can be directly caused by the emotions. In this connexion Shulack suggests that the vegetative centres in the hypothalamus and the vital centres of the medulla may be the seat of a disturbance of unknown nature or the point of attack of a hypothetical toxic substance. No pathological changes have, however, been found in these regions. Most of the authors regard their cases as schizophrenic, though Derby⁷ speaks also of manic-depressive psychoses taking this course. Stauder thinks these cases constitute a special clinical group of "fatal cataonia," and thus revives under a new name the "delirium acutum" of the psychiatry of last century. Scheid, on the other hand, considers them pronounced examples of the schizophrenic illness in which the bodily symptoms otherwise are latent and difficult to assess. He describes similar "febrile cyanotic episodes" as transient phases in schizophrenia, and regards them as critical states comparable to coma in diabetes. It is difficult to see how the ambiguous and obscure pathological changes found in these acute psychoses can be of any help in investigating the pathology of schizophrenia, but there is always the temptation in medicine to explain the unknown by the unknown.

DURATION OF IMMUNITY AFTER DIPHTHERIA PROPHYLAXIS

The degree and duration of immunity produced by any form of preventive vaccination can be measured either by estimating antitoxins or other antibodies circulating in the blood of the vaccinated person or by determining whether the expected incidence of the specific diseases among the vaccinated individuals is reduced during a short or long period following immunization. In estimating the protection conferred by immunization against diphtheria the first of these methods has served well. The second method has been mostly used in the case of small-pox, and among people who are constantly exposed to the chance of infection with small-pox it is the custom in some places to vaccinate in infancy and revaccinate perhaps on two occasions, at seven and fourteen years after the first inoculation. Is there any need for periodic revaccination against diphtheria? The question has been asked many times, and has been discussed by Parish and Wright.¹ S. Frant² has shown that in New York, where immunization has been employed on a very large scale during recent years, the proportion of cases of diphtheria in patients over 15 years of age has increased, though a substantial number of these patients had been inoculated earlier in life. It is not clear that all the children had been tested after inoculation and proved to be negative to the Schick test, but probably this assumption is near the truth. Dr. Frant has suggested that children should be actively immunized in the first year of life and subsequently Schick-tested, a second Schick test being undertaken three years later, apparently just before the child goes to school. If this second test gives a positive result, his suggestion is that one further dose of prophylactic should be administered. D. T. Fraser³ made a somewhat similar proposal in 1936. The ideal policy would be immunization in infancy with periodic tests every four or five years, but this would be troublesome and would almost certainly prove impracticable. Most doctors would steer a middle course between the present practice of one immunization against diphtheria in infancy and periodic revaccination, as is customary against typhoid fever or small-pox. A child who has once been vaccinated against diphtheria has, even after he may have reverted to the Schick-positive condition some years later, a vivid "potential" immunity, and will quickly become Schick-negative again after the injection of one dose of prophylactic or after a sub-clinical infection. As Chesney and others have shown, the injection of two doses of potent alum toxoid, separated by a proper interval, produces the Schick-negative condition in virtually all children injected; thus the Schick test—except for purposes of research and periodic control—might well be omitted when this antigen is used. This would reduce the work of the administrator considerably, and the saving of a visit by the mother and child at this stage might well make them more responsive to the suggestion that it would be a simple form of insurance to bring the child again

for one injection of prophylactic just before starting school life, with its greater risk of exposure. Where some such policy is not adopted the medical officer of health, if there is evidence that a severe wave of infection is occurring locally, as part of his immunization scheme should consider urging the injection of one dose of prophylactic in the case of all children who have been immunized in infancy.

SULPHANILAMIDE AND SERUM

Most of the infections amenable to the action of sulphanilamide were previously treated with serum. Where serum treatment was always of doubtful value, as in the majority of streptococcal infections, it has already been almost forgotten; on the other hand, in some types of pneumonia and in meningococcal meningitis, where the efficacy of serum treatment was fully established, it has now become an important question whether chemotherapy is merely to reinforce or completely to supersede it. There is both experimental and clinical evidence that the two treatments combined are more effective than either alone. This is to be expected, but it does not follow that both should be employed in favourable cases; if one specific remedy will serve it is a mistake to employ two, especially if the second is expensive, difficult to administer, and apt to cause unpleasant after-effects. In severe and desperate cases every available therapeutic weapon should be brought to bear, and what this may achieve is well illustrated in a report by M. Finland, J. W. Brown, and A. E. Rauh⁴ on ten patients with pneumococcal meningitis treated with both sulphanilamide and serum, of whom six recovered. It seems to be beyond question that 2-(*p*-aminobenzenesulphonamido)pyridine ("M and B 693") is much more effective in pneumococcal infections than is sulphanilamide, and it is arguable that favourable cases of pneumonia may justifiably be treated with this drug without resort to serum. The contrary attitude to this has recently been voiced in this *Journal* by Fleming,⁵ who has also published evidence based on *in vitro* experiments that the combined action of this drug and of serum is greater than that of either alone. A further plea for combined serum and chemotherapy is now made by E. F. Osgood⁶ on somewhat similar grounds. Osgood has previously advocated the use of a bone-marrow culture medium for studying chemotherapeutic action on streptococci, and he has now employed this method for the pneumococcus. What his experiments show is that the growth of this organism is suppressed to a greater degree in this medium by anti-pneumococcal serum and sulphanilamide together than by either acting separately. These, and more particularly some further experiments in broth, would carry more conviction were it stated that the serum used contained no preservative. These experiments raise another question of wider interest. Their object is to imitate

far as possible *in vitro* the conditions which obtain in the body, the test mixture containing not only the therapeutic agent under investigation, a suitable nutritive fluid, and bacteria, but living leucocytes. Similar conditions are secured by the "slide-cell" method employed by Fleming, in which drug or antiseptic in different dilutions and bacteria are mixed with fresh blood. If the results obtainable by these proceedings are valid, as they doubtless are in principle, it is desirable that a standard method of this kind should come into more general use.

IDENTICAL CANCERS IN IDENTICAL TWINS

An interesting addition to the records of cancer in identical twins is reported from the Mayo Clinic by Phillips.¹ One twin had a carcinoma in the right breast in 1927 and another carcinoma in the left breast eight months later. The other twin had a lump in the right breast for which a simple mastectomy was performed; in 1932 there was a recurrent carcinoma on the right side and another carcinoma was present in the left breast. Radical operations were performed on both twins, who are now well and apparently free from cancer of the breast. In 1937, however, the first-mentioned twin developed bilateral papillary adenocarcinoma of the ovaries. Will ovarian cancers develop in the other twin? The immediate problem for the surgeon is to decide what should be done to safeguard the second twin. Phillips suggests prophylactic oophorectomy or deep x-ray treatment, but does not feel justified in advising hysterectomy. Usually, if a cancer develops in one of a pair of identical twins, the other twin has a cancer of the same type in the corresponding organ, either at the same time or soon afterwards, but Phillips quotes a case of Kaplan's in which carcinoma of the breast had not been reproduced in an identical twin after six years. In the future drastic preventive measures may be advised without hesitation; the accumulation of carefully observed instances will supply the guide.

FATALITY RATES IN TUBERCULOSIS

In an interesting analysis of the present trend of case fatality rates in tuberculosis² Drolet shows that the ratio of deaths to new cases of tuberculosis reported in various communities has varied little in the past twenty years, a period during which the incidence and mortality of the disease have been declining steadily. Similarly, no variation was found in this ratio when it was calculated on the basis of the new cases reported and the survivors two years after notification, the period during which most of the deaths occur. Since the ratio of deaths to cases is comparatively high in children under 5, low in the age-period 5 to 15, and then rises steadily with age, the possible influence of a change in the age distribution of the populations had

to be eliminated. Drolet shows that the differences between the age of patients or age at death now and formerly are not great enough to modify materially the fatality rates of the communities investigated. Persons dying from tuberculosis now are, on an average, slightly older than formerly. Passing to the influence of treatment on the fatality rates, Drolet finds that the mortality ratio to the total discharges among cases treated in sanatorium or hospital since 1910 has tended to fall in New York. In England, on the other hand, the mortality ratio in "approved residential institutions" was 11 per cent. in 1927, and has risen steadily to 19 in 1936. The proportion of all tuberculosis cases "isolated" in hospitals is several times greater now than it was some time ago: in the United States it has risen from 4 per cent. in 1915 to 25 in 1934; and in England, from 8 per cent. in 1921 to 17 in 1934. This he considers the most important factor in the fall in the tuberculosis mortality. Finally, Drolet says that sanatorium or surgical treatment of pulmonary tuberculosis would seem so far to have had little effect upon the case fatality rates of the entire tuberculous population in the communities he has studied. But this finding in regard to the surgical treatment (including artificial pneumothorax) of pulmonary tuberculosis in no way detracts from the value of collapse therapy, for correctly applied collapse therapy is still too recent a measure to allow of the study of its influence on case fatality.

THE MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS

We publish in the *Supplement* this week, at the request of the General Medical Council, a list of the names of those medical practitioners who have not replied to the Council's inquiries as to the accuracy of their postal addresses. Any practitioner, wherever resident, whose name is included in this list should communicate at once with the Registrar of the General Medical Council, 44, Hallam Street, Portland Place, W.1, or, if originally registered in Scotland, with the Registrar of the Scottish Branch Council, 44, Queen Street, Edinburgh, 2.

The second W. E. Dixon Memorial Lecture will be delivered by Sir Frederick Banting, F.R.S., in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole Street, W., at a meeting of the Section of Therapeutics and Pharmacology on Tuesday, October 11, at 5 p.m. The subject of his lecture is "The Immunity Aspect of the Tumour Problem."

The Harveian Oration before the Royal College of Physicians of London will be delivered on St. Luke's Day, Tuesday, October 18, at 4 p.m., by Sir Edward Mellanby, M.D., F.R.S., whose subject is "The State and Medical Research."

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

INFECTIONS OF THE HAND AND FINGERS—II

BY

NORMAN C. LAKE, D.Sc., M.D., M.S., F.R.C.S.

Mode of Infection

Infection may reach the fingers and hand in many ways. The most obvious and important is by penetrating and lacerated wounds, especially those produced by the prick of needle or pin or other sharp-pointed instrument. The reason why penetrating wounds of this type appear to be more prone to the development of infection than others is probably because the organisms are implanted along the long narrow track through which the natural flushing of protective serum and exudates is impossible. There can be little doubt that a large number of organisms are mechanically removed during the penetration of the tough superficial layers of the skin, especially on the volar aspect, otherwise infection would be even more frequent. Extensive lacerated and incised wounds of the hand, too, are probably more likely to lead to infection than in many other regions of the body. This may be due to the fact that many of the divided structures retract well away from the wound, and so carry organisms into parts which are neither flushed by the natural transudation of lymph nor easily reached by such primary antiseptic measures as may be used.

The second mode of origin of infection is from small superficial skin lesions, especially around the nails. In particular a "hang-nail" is a common portal of entry. Dermatological lesions of the skin also may form the primary source of infection, and these, of course, not infrequently prove to be of vocational origin. The question of blood-borne infection of the fingers and hand is a moot one, since minute portals of entry can so easily be overlooked. There are, however, exceptional cases in which it appears beyond doubt that the infection reached the part from some other focus via the blood stream. In all cases of apparently spontaneous infection the suspicion must arise of an underlying constitutional condition, such as diabetes, or of a pyaemia. These suspicions must obviously be confirmed or confuted before any surgical means of treatment are entertained.

Spread of Infection

It will be readily recognized that infection of one part or tissue may arise by spread from another; thus infections of the palmar spaces often follow a primary infection in the finger. In many instances this spread is a continuous one, the infection extending along the subcutaneous tissues or in the thecal sheaths, which latter may subsequently burst at their proximal ends into the cellular tissues of the palm. It is because extension of this type tends to be, at least temporarily, controlled by certain anatomical features that so much attention has been paid to these in the previous section. In other cases the spread is a discontinuous one. Here the organisms travel from the fingers along the lymphatic spaces or vessels, are arrested in the palm, or even higher, and there set up a new zone of infection. Spread may occur

distally as well as proximally; the classic "Kanavel hand" arises when deep palmar suppuration extends distally along the lumbricales to the web spaces, there to discharge spontaneously through multiple sinuses.

Sometimes infection is complicated by the retention of foreign material in the wound; in these circumstances its detection and removal may constitute an important part of the treatment. Metallic foreign bodies are obviously easily displayed and localized by radiography. Cloth, leather, etc., can only be discovered by thorough exploration of the wound. A very common foreign body is glass: the coarser varieties contain enough lead and other heavy materials to render them more opaque than the body tissues to the rays, but the finer varieties may give such a poor shadow as to be easily missed. Wood, another common foreign body, is as easily penetrated by the rays as the body tissues, and therefore cannot easily be detected by this means. Luckily, splinters of wood often have a coating of paint or other opaque material, which aids greatly in their detection.

Infections arising from injury may also be complicated by lesions of tendons, nerves, vessels, or other bones. Such complications must be recognized in the early stages, since they may necessitate considerable modification of the treatment otherwise proper to the case.

Chronic Infections

Chronic infections of the hand fall outside the scope of this article, but as they may enter into the question of differential diagnosis it is necessary to state here the chief ways in which chronic infections manifest themselves. In syphilis the primary chancre may appear on the finger-tip, especially in dentists, doctors, nurses, and others having to deal with these cases. The palm of the hand is a common site for the appearance of the secondary rashes, but as these are always bilateral they rarely occasion mistakes. Tertiary lesions in this situation are exceedingly rare, but gummata arising in the periosteum of the bones and even from the soft tissues have been recorded.

Tuberculosis may affect the hands in three chief ways. The skin may be the seat of a local tuberculous process due to direct implantation of the organisms in surgery, pathologists, and the like. This gives rise to the well-known verruca necrogenica. In children a tuberculous osteitis of the metacarpals or phalanges produces the so-called tuberculous dactylitis (spina ventosa). The diagnosis of this condition is confirmed by radiography, an unusual feature being the laying down of fresh bone under the periosteum, even in the absence of a secondary infection. In later life tuberculous infection of the palmar bursa may arise.

In this the exudation distends the whole palmar space, and so appears as an hour-glass swelling, partly distal and partly proximal to the annular ligament, and through fluctuation. In this variety of tuberculous tenosynovitis the production of numerous "milk-cream" ("rice") bodies is usual.

Other chronic infections have been known to appear in the hands, but their incidence is so rare that they are ignored.

Diagnosis

The diagnosis of infection of the hand and fingers is usually self-obvious. The determination of its site and anatomical localization, however, is much more difficult and of far greater importance. It has already been pointed out that the position of maximum swelling is not necessarily a guide to the location of the infection. Thus in inflammation of the palmar and thenar spaces the maximum swelling is always seen in the dorsum of the hand. The position of maximum tenderness is of greater value, but even this gives no indication of the depth of the infection. In the more superficial infections—that is, subcuticular, subcutaneous, or subungual whitlow—the limits of the infection are usually clear. When the thecae are involved there is swelling corresponding to the anatomical limits of the particular sheath involved, and there will be pain upon all movements of the digit, both active and passive. It is extremely important to note the range of movement over which pain is elicited, for pain upon movement in one direction only may arise when the infection lies outside the sheath if the inflamed part is compressed by the movement. In these cases, however, movement in the opposite direction usually brings relief, which of course is not the case when the theca is involved. Inflammation in a joint, too, may give rise to pain on all movements, but here the localization of the swelling to the vicinity of the joint enables the distinction to be made. In this instance pressure along the longitudinal axis of the digit is painful, whereas this is practically painless when the theca only is involved. End pressure upon the nail elicits local pain in the case of onychia or when the terminal phalanx is affected. Suppuration in the nail bed can often be seen through the translucent substance of the nail: a greenish-yellow area indicates the site of the pus.

Infections of the palmar and thenar spaces produce a fullness of the corresponding site of the palm, with obliteration of the normal hollow (cup of the palm) and local tenderness. If the anatomical limitations of these spaces be remembered there will be little difficulty in detecting which space is involved, but in addition the situation of the swelling in the web spaces and on the dorsum of the hand will afford corroborative evidence. The inner three web spaces are affected when the palmar space is involved, the first web space and sometimes the second when the thenar space is involved. If the thecae are not also infected a limited degree of movement of the fingers is possible without pain.

Infection of the palmar bursa (common flexor sheath) also causes fullness in the palm, best marked on the ulnar side. This can be distinguished from infection of the areolar space by noting that the swelling extends above the annular ligament, and that the movements of all the fingers are extremely limited and painful in the early stages. A swelling proximal to the annular ligament may be due to infection of the deep space of the forearm by extension from the palmar space. This is distinguished from a bursal swelling by the fact that it is less well defined and arises at a later stage of the disease when the palm is already extensively involved.

To complete the examination a search must be made for the presence of lymphadenitis in the axillary glands, rarely in the epitrochlear also, and for lymphangitis. The superficial lymphatic vessels for the most part travel in a spiral fashion, passing from below upwards and inwards around the forearm. The red, tender, and indurated streaks of a lymphangitis follow this course.

Finally, the general condition of the patient must not be overlooked. The extent of increase of temperature and pulse and the occurrence of rigors are all important diagnostic features.

Pre-operative Considerations

The foregoing section has dealt with the anatomical limitations of an infection, but before rational treatment can be undertaken it is necessary, in addition, to form a conception of the type and virulence of the infecting organisms: the conduct of the case will depend upon this as well as upon anatomical considerations. The organisms most commonly found are, of course, staphylococci, streptococci, and more rarely *B. coli*. Of the former the *aureus* variety has a special virulence which may approach that of many streptococcal infections; it may produce a lymphangitis not unlike that of a streptococcus. The well-known predilection of this organism for bone will naturally arouse a suspicion of some bone involvement, but in the hand this distinction is of less importance than it would be in many other regions. A lymphangitis can, however, usually be accepted as evidence of a streptococcal infection, especially if it be associated with a widespread infection which displays little tendency to localization or suppuration, if the patient develops rigors, or if his general condition appears to be unduly bad in proportion to the extent of the lesion. Sometimes, when a wound is already present, the actual organism may be identified by bacteriological examination, and when possible this should be done. Frequently, however, the nature of the infection has to be decided from clinical observation only. In the presence of lymphangitis, lymphadenitis, high temperature, and rigors the infection may be assumed to be a streptococcal one and treatment instituted accordingly. If involvement of bones or joints is suspected, a skiagram should be taken before the diagnosis is considered complete. A similar precaution should also be observed when the possibility of a foreign body arises. In the case of lacerated wounds a careful search must be made for evidence of damage to nerves or large blood vessels.

It cannot be too strongly urged that the preliminary examination should be thorough, for only in this way can a complete picture be formed that will enable one to deal with the case efficiently. It has already been remarked how important the hand is from the economic point of view; if the maximum of function is to be retained in an infected hand there must be no hurried surgical intervention before the case has been studied completely.

It has for long been customary to classify whitlows into subcuticular, subcutaneous, subperiosteal, subungual, and thecal, but, although this subdivision has its virtues, it conveys an idea of detachment that is quite alien to the general tendency to spread from one structure to another which these infections display. Such a detached pathology is apt to lull one into an unjustified sense of security, which may cause delay in the recognition of important extensions and so produce tragic results.

Treatment

The treatment of these cases depends upon the localization and the nature of the infecting organism. The general principle of rest to an acutely inflamed part, however, is applied to all, whether operative treatment is necessary or not. Rest tends to limit the spread of the infection, and is particularly useful when the thecae are threatened or involved. It is achieved by appropriate splinting. Often the best form of splint to use is that

constructed of stout wire bent by the surgeon to suit the individual requirements of the case while allowing the necessary dressings, baths, etc., to be carried out without disturbance. There is no need here to detail the construction of these splints: their efficacy is often a measure of the mechanical ingenuity of the doctor. In some instances plaster slabs may be moulded to immobilize larger parts; they, too, must be applied in such a way as to allow the dressing to be carried out without movement of the joints or tendons.

If the suspicion arises that the case is due to infection with a streptococcus, special caution is necessary in its conduct. Owing to the fact that violent streptococcal infections, here as elsewhere, are associated with some degree of septicaemia in the earlier stages, and that there is little tendency to localization, operative treatment, with certain exceptions to be mentioned later, should be avoided. The old idea of making multiple incisions into the infected areas "to relieve tension" has little to recommend it, and may be definitely harmful by helping to spread the infection and breaking through any resisting barrier which may be forming. In the initial stages the treatment of such cases may be along general lines. The recent introduction of drugs of the sulphonamide group has placed in our hands a potent weapon for dealing with streptococcal infections. Since, in reasonable dosage, they appear to be devoid of any serious untoward effects, their use is justified in suspected cases, even before the nature of the organism has been definitely proved. The original materials, given by injection, have been largely supplanted by others for oral administration. Prontosil, prosectasin, streptocide, etc., may all be given in $\frac{1}{2}$ -grain doses four times a day. Sulphaemoglobinaemia and albuminuria have both been reported following the use of these drugs, but the special precautions to be taken will be considered in a future article in this series. Antitoxic streptococcal sera are also of proved value in these streptococcal cases, and should be used when other means fail to arrest spread. Lymphangitis and lymphadenitis are similarly dealt with. If the infection is a very superficial one (erysipelas) it may be reached by ultra-violet irradiation, which has a definite limiting effect and is of considerable value.

The rule that streptococcal infections are not to be treated by operation is subject to two important exceptions. If the vitality of a digit is threatened by the extreme tension of the exudate, which is obviously interfering seriously with the blood supply, some small incisions into the subcutaneous tissues are proper in an attempt to reduce the tension and so save the finger. In cases of this type the simultaneous administration of the sulphonamides is advisable to avoid blood-stream infection. The second indication for operation arises in the later stages, when frank suppuration has occurred. The appearance of localized pus in a streptococcal case is a sign that the patient's resistance is dealing adequately with the infection, and in these circumstances drainage may be instituted as for other infections.

With these important exceptions infection of the hand and fingers should receive energetic surgical treatment in as early a stage as possible. Damage may be done both by delay and by too vigorous and extensive initial treatment, but there can be no doubt that the commoner errors are those of delayed and timid surgery. An early infection is sometimes dealt with by a minute incision under an ethyl chloride spray which lets out a bead of pus but fails to arrest spread at the periphery. The surgeon probably thinks that a larger incision will take a long time to heal, forgetting that a widespread infection, inadequately treated, will take much longer still and may

lead to great disability. These cases must be attacked in no half-hearted way; but as a corollary to this it is most important that the surgeon should have a clear idea of the aim of the operation and of the anatomy of the parts, so that he may design his incisions to produce proper drainage without endangering any important structures, spreading infection, or producing disability by his very procedure. Every case must be carefully worked out on its merits, but there are certain general rules which form a valuable guide in the majority of instances. It must be stressed that all operations of this type should be performed deliberately under full general anaesthesia, with good illumination, and, preferably, in a properly equipped operating theatre. To attempt to drain an infected hand or finger, other than a very superficial infection, in the surgery or the casualty ward under a short gas anaesthesia is courting disaster. Local anaesthesia is not usually suitable for these cases, with perhaps the exception of the terminal phalanx, where regional anaesthesia may be produced by circumferential infiltration at the base of the digit. The use of the ethyl chloride spray, even for fairly superficial infections, is not to be recommended: the local freezing devitalizes the parts and facilitates the spread of infection. Gas-and-oxygen or evipan anaesthesia is quite adequate for these cases, and should supplant all local measures.

A tourniquet should be used only with the greatest of reluctance for fear of devitalizing tissues; if it is employed at all it should remain on for a short time only, and in no circumstances should Esmarch's bandage be applied.

(To be continued)

MEDICAL DEFENCE UNION

At the annual meeting of the Medical Defence Union, held on September 27, it was announced that during the year 1,627 new members had been elected, and that in July last the total membership stood at 21,231. The number of cases handled during the year was 1,814. The investments now amount, at market value, to over £102,000.

The Matrimonial Causes Act

One matter to which the Council of the Union has given careful consideration during the year has been the application of the Matrimonial Causes Act, 1937. The Council aligns itself with the British Medical Association in the view that when a practitioner is approached for an opinion by a declared prospective petitioner as to the incurability of the mental condition of the respondent or as to a medical condition existing at the time of marriage, he would be well advised to decline to express such an opinion, except at the direction of the court, or to a guardian *ad litem* if appointed though he might conceivably place his records of the case at the disposal of an independent medical expert nominated by the petitioner or by his authorized legal adviser. It is anticipated that there will be developments affording practitioners a fuller degree of protection than they now possess, and permitting the proper operation of the Act without the risk of an action for defamation being brought against the practitioner. One suggestion is the establishment of a panel of medical examiners, as at present in nullity suits. Another is that Section 16 of the Mental Treatment Act, 1930, should be applied to preclude any person starting an action against a certifying practitioner until the court is satisfied there is substantial ground for his contention.

Allegations of Negligence

The annual report includes a useful series of typical cases dealt with during the year. It illustrates incidentally the

variety of methods adopted by patients when they want to evade payment of a doctor's account. One of the most common is to quote another doctor's diagnosis as evidence of improper diagnosis and treatment. Of the 184 cases handed over to the Union's solicitors (Messrs. Hempsons) to be dealt with, about half involved charges of negligence, the majority of these being raised by way of set-off or counterclaim, but in no case did the set-off or counterclaim succeed. In one or two cases actions have been threatened on the ground of complications following an operation, after which there had been non-absorption of a stitch. The Council has always felt that this is a matter for which the surgeon cannot in any way be held responsible, as it is due to a defect in the material which he cannot anticipate.

Unauthorized Examinations

An unauthorized operation, save in an emergency, or even an examination may constitute an assault in law, and members of the Union are advised to make sure when instructed to examine a patient on behalf of a third party that the person to be examined is fully aware of the circumstances and that they have his permission to examine him and to report to the person on whose behalf the examination is made. A case is related in which action was threatened against a practitioner who carried out the examination of a man without his sanction. The practitioner was medical officer to a football team and was instructed on behalf of the management to examine a player whose transfer was under consideration. At the time the man was suffering from pneumonia, and at the suggestion of the man's wife, who said that her husband would be distressed about the contemplated transfer, the doctor unwisely pretended to be deputy for his ordinary doctor. In due course the man discovered the deception, and raised an ingenious claim on the ground that the examination had been harmful to him in that he had been disturbed and his body uncovered. When it was realized that the Union was prepared to defend any form of action, however, the claim was abandoned.

Commutation of Subscriptions

At the annual meeting the president, Mr. E. L. PEARCE GOULD, mentioned among other matters the scheme, recently introduced, whereby members can commute their remaining annual subscriptions by making one payment related to the length of their previous membership. Although the scheme had been published a short time, several members had already availed themselves of it.

The President referred also to the volume of work falling upon the Council at its monthly meetings, resulting in prolonged sessions. He told the meeting how the Council had decided to establish a Council Committee, to which would be delegated all the business and routine matters, leaving the Council free to deal with live and important cases, for the conduct of which the solicitor (Mr. Hempson) is personally responsible. This alteration in the allocation of the business of the Union, dividing it between two separate bodies—the Council Committee and the Council—has resulted in the Council being able to conclude its business in the afternoon at a reasonable hour, and also enabled it to give fuller consideration to urgent affairs requiring immediate attention.

According to the *Bombay Chronicle* the Government of Bengal and the Public Health and Local Self-government Department have decided to establish a model health unit at Singur in the district of Hooghly during the current year with a staff of one medical officer of health of the status of first-class health officer, one lady doctor, four health visitors, eight midwives, four sanitary inspectors, and two clerks and menials. The average annual cost for maintaining the unit (including contingent charges) is estimated at about Rs. 30,000, towards which the Rockefeller Foundation has offered a contribution for the first five years.

Nova et Vetera

AN AMERICAN "PHYSIOLOGICAL" SOCIETY OF 1837

Those familiar with the history of the Physiological Society in this country and the jubilee of the International Congress of Physiologists this year will probably be startled by the opening sentence of an article by Dr. Hebbel E. Hoff and Professor John Fulton of Yale: "A hundred years ago the first physiological society in the world was founded in Boston, under the name of 'The American Physiological Society.'" The explanation is simply that it was not on the lines of a serious scientific body of investigators. It was founded in 1837 by William Andrus Alcott, who after one year's work obtained a diploma from the Medical Institution of Yale College, was a keen educationist, and became president of the society, and by Sylvester Graham, who among other occupations had been the general agent for a temperance society, a clergyman, and a public lecturer on the "science of human life," in which he advocated abstinence from all drink except water, a vegetable diet consisting principally of bread at least twelve hours old made from scarcely ground wheat, and a cheerful atmosphere at meal times. The advertised object of the society was to acquire and diffuse a knowledge of the laws of life and of the means of promoting human health and longevity. One attempt only, and that quite abortive, was made to advance the knowledge of physiology by means of experiment. The society did not last more than three years, and half-way through its life had a membership of two hundred and fifty-one, including ninety-three women; in Alcott's words, most of the members "were more or less feeble, and a very large proportion of them were actually suffering from chronic disease when they became members of the society. Not a few joined it, indeed, as a last resort, after having tried everything else."

SALE OF A CHILD FOR DISSECTION

Under the heading "Singular Depravity," the *Annual Register* for July 27, 1838, contains a record of the following remarkable case.

"A very singular trial took place at the Cork Assizes. A woman was found guilty of offering to sell a child (which she had for some time supported out of charity) for the avowed purpose of dissection. The medical man to whom she made the extraordinary offer arranged a second interview at which he had a policeman concealed. She entered again deliberately upon the bargain, whereupon she was taken into custody. It appears that she was perfectly sober, but she had made the unfortunate child drunk, and when it became alarmed and cried she urged the doctor to give her something at once that would settle her, telling the poor creature that the gentleman would give her something sweet. She was found guilty. Death is the penalty provided by the statute. The judge, however, held out hopes of mercy. We do not exactly see on what grounds."

The issue of the case is not recorded.

John Wolcot, the bicentenary of whose birth occurs this year, took the M.D. Aberdeen in 1767, and two years later was ordained priest. As physician in general to horse and foot in the island of Jamaica he failed to achieve success or popularity through his frank assertion that the doctor can do little more than watch Nature and give her a shove on the back if he sees her inclined to do right. Returning to England, he soon exchanged physic for poetry, writing numerous coarse satires under the name of Peter Pindar, "a distant relative of the poet of Thebes." He died in 1819.

Hoff, H. E., and Fulton, J. F. (1937). "The Centenary of the first American Physiological Society, founded at Boston by William A. Alcott and Sylvester Graham." *Bull. Inst. Hist. Med.*, 5, 687.

OPENING OF THE NEW SESSION

NEW MEDICAL SCHOOL AT ABERDEEN

ADDRESS BY LORD DAWSON OF PENN

The new Medical School at Aberdeen University was opened on September 28 by Viscount Dawson of Penn. The school is at Foresterhill, on the outskirts of the city, on the 117-acre site of the joint hospitals' scheme, where the Royal Infirmary, the Hospital for Sick Children, and the Maternity Hospital are concentrated. Lord Meston, Chancellor of the University, presided at the opening ceremony, and among others present were the Lord Provost, the Marquis of Aberdeen, Dr. Thomas Fraser, President-elect of the British Medical Association, and Dr. G. Mitchell, President of the Aberdeen Branch. Lord Meston said that four centuries of progress looked down upon their University—centuries of steady progress from mediaeval empiricism to a humane and intelligent treatment of human suffering—and yet they might be now only on the threshold of medical knowledge and surgical skill. The present ceremony was one of rededication, and their earnest prayer was that the new building would help them to serve mankind as their forefathers with dimmer lights and narrower means had striven to do.

A Wider Comprehension of Medicine

Lord Dawson began by congratulating Aberdeen on its enterprise, saying that its regional hospital scheme should be a pattern for Great Britain in the mapping of areas. The site offered an opportunity for giving reality to the wider comprehension of medicine. Curative and preventive medicine were still separated too much into compartments. They should be brought together, taught together, and practised side by side. At present preventive medicine was inadequately taught, and was nothing but a postscript to the student's career. Such a site as that at Aberdeen offered a basis for the broadening of medical education to the profit of the community. It would be easy for the city, if in its wisdom it were so minded, to erect on the site a building which would house the most important communal clinics. Thus from the very first the students would breathe the atmosphere of preventive medicine. He pointed to the value of the team work rendered possible by such a plan, and also to the economy in expenditure.

Contrasting the conditions as they existed to-day with those obtaining a few years ago, Lord Dawson said that there had been, taking the country as a whole, a gradual growth of medical and hospital services which, however individually excellent, had become a medley of separate efforts. These services fell under the headings of communal services and clinics, voluntary hospitals, and municipal hospitals. The communal services represented a fine achievement which stood to the credit of local authorities and their medical officers and conferred substantial benefits on the common health. Their isolation and divorce from the general body of doctors in the district was a disadvantage. They needed to be brought into the texture of medical practice. It was useless to expect the general practitioner to think in terms of constructive health unless the clinics and similar services were open to him.

With regard to the voluntary hospitals, these were living societies which had grown up with the British people. Provided the "dead wood" was periodically cut out, to allow them to languish for want of material support or to let them and all they stood for die by absorption into local authorities would be alien to our genius for social evolution and a damage to our national well-being. The faults of the voluntary hospitals in recent days had been their slowness to widen their horizon so as to include

preventive medicine and its ideals. Nor could they stand as disconnected institutions; they must play their part in a comprehensive scheme of medical services. It could not even be claimed that the possession of teaching schools conferred the right to exclusiveness, for the function of teaching had been extended to the municipal hospitals and clinics.

The municipal hospitals had come into existence during the last eight years, were steadily growing in numbers and importance, and were serving the community well. But their existence had intensified the necessity for co-operation. With voluntary and municipal hospitals working side by side, it meant that there were two sets of hospitals and two sets of doctors in the same community, and confusion and conflict must result.

The remedy was suggested by that enterprise at Foresterhill. There the communal services would soon be represented by the ante-natal clinic, and, he hoped, a municipal wing to the maternity hospital. An orthopaedic service run jointly by the city and the university would be very desirable; and thus the scheme would grow. Here was a medical college fully equipped for the teaching of the sciences basic to the art of medicine, and an assemblage of special hospitals gathered round the Royal Infirmary. What finer opportunity for clinical training could there be?

Lord Dawson concluded with some remarks on the duty of leadership by medicine in regard to improvement of the human stock. The smaller the birth-rate the more it was necessary to select for quality if the race was not to deteriorate.

On the proposition of Principal W. Hamilton Fyfe, seconded by Professor David Campbell, a vote of thanks was accorded to Lord Dawson for his address.

WESTMINSTER HOSPITAL

DR. HUTCHISON ON THE MEDICAL CAREER

The inaugural address at Westminster Hospital Medical School was given (for the first time in the handsome new building in Horseferry Road) on October 3 by Dr. Robert HUTCHISON, P.R.C.P. He compared the medical career to a race, and as one who had been over the course, offered some advice on the points where new entrants might "take a toss."

The reasons for entering upon a medical career, Dr. Hutchison said, were various, but whatever they were in the case of the young fellows before him, he congratulated them on their choice. He did so on the mundane ground that medicine was an interesting, intriguing, even amusing occupation, in which, although with all its labours and languors they might often know fatigue, they did at least escape boredom. It also gave opportunity for the exercise of all one's powers, physical, mental, and moral, and offered an admirable field for the study of human nature in the raw. Further, the prizes in the race were quite substantial. On the whole, doctors were well paid, and they had the further advantage, that their skill, once acquired, was marketable all over the world. Some of them, starting the race, might be dismayed by the number of competitors. When he himself started half a century ago there were 400 men in his year at Edinburgh. Large though the number of entrants had been in recent years, saturation point did not seem to have been reached, and the scope and amount of medical work were always increasing. Dr. Inge had said that, though democracy might starve the clergy and practitioners of the arts, it would always demand doctors.

Handicaps and Hurdles

This medical "race" was a handicap. Some carried weight all through the course because of poor health, lack of intelligence, inborn laziness, shyness, or a bad manner. Others might be burdened by poverty. Perhaps that was not a burden, but a spur. Poverty was the only advantage which a rich parent could not give his son. The race was not really very long. Eight laps of five years each would see the end of it for most—a long time to look forward to, but short in retrospect. The first lap was a hurdle race, the hurdles being the examinations. These were inevitable, no one had suggested any substitute for them, and, rightly regarded, they added interest and even excitement to the race. The business of the student was so to run as to take them in his stride, and this he could do easily enough if he went steadily on, not in a succession of spurts.

Dr. Hutchison refused to diverge into a discussion of "that boring subject" medical education, but if he himself had any guiding principle in teaching the medical art it was summed up in the saying, "You can't have the terriers too soon at the rats"—in other words, get as early into contact with patients as possible. None the less, teaching was of importance, and considering that members of hospital staffs were appointed chiefly for professional and not pedagogic skill, it was surprising that on the whole it was so good.

Short. Cuts

He deprecated the shirking of the last hurdle or two by being content with a simple qualification to practise instead of going on to a degree. He knew the reasons commonly advanced for the short cut. It was praise-worthy of a young man to desire not to be a charge on his parents for longer than he could help, but he thought it mistaken. A parent who had maintained his son to the age of 23 could surely continue doing so to the age of 23½. To suppose otherwise was to believe him capable of "swallowing the cow and choking on the tail." And the public liked "the good old M.D."

Many blind alleys awaited the young graduate—"research" posts of one kind or another, and small institutional jobs. He advised them to shun the lure of the laboratory unless they felt the curiosity and restlessness of the born researcher. Another danger against which he felt it useless to warn them, and yet warn them he must, was the premature engagement. He knew the sentimental argument—"someone to work for," and so on—but at this stage of the race he travelled fastest who travelled alone. Here "a young man married was a young man marred." As Osler used to say, they must learn to keep their emotions in cold storage.

Having escaped these and other hazards, the newly qualified practitioner had to choose his line of country, and, as the German proverb said, "*Wahl macht Qual*" (choice is torture). It was as well to have a look round first and get experience by holding resident appointments, but such posts should not be held for too long. "Don't become an appointments addict." In the house of medicine there were many mansions, but the majority, he supposed, would run the race in general practice. The general practitioner was the soldier in the front line, withstanding, often single-handed, the first assault of disease. He was all the more to be envied on that account. "A man in a good country practice particularly is a real doctor, not a mere sorting machine, for consultants or hospitals, and is probably living as full, useful, and happy a life as our profession offers."

Dr. Hutchison put in a word of warning about the quack—the man who got on to the course without having first jumped the hurdles. They might say to such, as Christian said to Formalist and Hypocrisy, who came from the land of Vainglory, "You walk by the rude working of your fancies." The quack should never be regarded as a real competitor, or his methods be imitated. He might

beat the qualified man sometimes in treatment, for patients still liked magic, but in matters of diagnosis the qualified man would always leave the quack standing.

The Winning Post

What made for success in the race? Not knowledge or manners, for a doctor might achieve a large practice without either! The French had a saying, "*Un peu de savoir, beaucoup de savoir faire, et assez de faire savoir*" (which he interpreted as a little knowledge, much tact, and a fair amount of advertisement). It sounded cynical, but it contained some truth. Possibly the power of inspiring confidence was the one thing needful. Some estimated success in terms of money, and it was foolish to say that that did not count. Some thought honours to be the hall-mark, but these were of little value unless bestowed by one's competitors. Perhaps Johnson was right when he said that "happiness at home" was the ultimate object of all ambition. So far as practice was concerned, that man had succeeded who had gained both the affection of his patients and the esteem of his colleagues. A friend of his, a suburban doctor, fell grievously ill and complete quiet was necessary. As soon as this was known his patients organized amongst themselves a rota of traffic controllers who, taking turns day and night, diverted all vehicles in the neighbourhood of his house for more than a week. He died before his time, but to have inspired such devotion was to have succeeded triumphantly.

But this was, after all, a race in which there were many kinds of success and no one winner, and perhaps it was not so much where one came in as how one ran that mattered.

"They win who never near the goal,
They run who halt on maimed feet.
Art has its martyrs like the soul—
Its victors in defeat."

After Sir STANLEY WOODWARD had moved and Dr. PULVERTAFT had seconded a vote of thanks to the orator, a report upon the progress of the school was given by the Dean, Dr. ADOLPH ABRAHAM. He referred to the building of the new Westminster Hospital. It might seem, he said, that the new surroundings were out of all proportion to the demands. Though the school was several times larger than in its old premises in Caxton Street, the number of students must be limited to a rigid maximum. Overcrowding did not occur at Westminster and never would occur.

ROYAL DENTAL HOSPITAL SCHOOL

MR. EASON'S ADDRESS

At the annual prize distribution of the Royal Dental Hospital (London) School of Dental Surgery on October 4 Mr. H. L. EASON, M.S., F.R.C.S., Principal of the University of London, gave an address on dental education and practice.

Mr. Eason pointed out that dentistry is essentially a technical profession, that what the public demands of it is expert technique and mechanical and professional skill. In this respect it differed from medicine but resembled surgery. In choosing a surgeon, a patient—especially if himself a doctor—wanted to be assured that the surgeon was an expert in the technique of the operation to be performed, and he was comparatively unaffected by any consideration as to whether the surgeon was distinguished in writing, teaching, or research. All he wanted to know was whether the operation could be performed skilfully, rapidly, and successfully. The same sort of question arose in dentistry. The dentist would make his living by his manual dexterity. At the same time he owed it to himself and to his profession to keep abreast of all advances in the knowledge of his subject and to maintain the academic ideal. The aim of dental education was to give to every

dental practitioner such a basic training in the elementary sciences and in the main elements of medicine, surgery, and pathology that he would be able to recognize from what affection the patient was suffering, also to recognize whether it was necessary or desirable for him to perform any operation within his province, and, finally, to know what to do and how to do it. The first two requisites would depend upon the thoroughness of his general education; the third upon his technical training and skill.

Should Every Dentist have a Medical Qualification?

Desirable as it was that every dentist should have a medical qualification and be a specialist in the same sense as an ophthalmologist, Mr. Eason said that this was impracticable at present. The number of dentists required for the service of the public was so great and the combined course of study for a medical and dental qualification so long and expensive that it would be hardly possible to find an adequate number of students with the necessary time and money. To the further question, whether it was desirable that every dentist should have a university degree in dentistry, he answered "Yes." The reason why so few students, in dentistry as in medicine, took a university degree as compared with the number taking the qualification of the licensing bodies was twofold, professional and economic—the longer and harder course of study for a degree, and the need for earning a living as soon as possible. But it would be found in practice that if the course for the degree were entered upon at the beginning of the student's dental career, it would not require more than ordinary energy and determination to get the distinction. Mr. Eason was referring in particular to the course of study for the B.D.S. of the University of London.

He went on to emphasize the need for postgraduate study. "Every self-respecting dentist should make an effort to take a course of postgraduate instruction at regular intervals throughout his professional life." He also paid a tribute to the dental surgeons who, during the last forty years or so, had done so much to raise the standard of dental education. It must be remembered that in dentistry there were practically no consultants; they were all practitioners, and the better a dental surgeon taught and the more time he devoted to teaching, the less time he had for his own practice and the more competitors he created. In medicine and surgery, on the other hand, the man who got a post on the staff of a teaching hospital and became a consultant got not only an acknowledged status in his profession but reaped a material profit. His students of to-day provided him with his living of to-morrow, and the better he taught the greater would be his reward.

Mr. Eason concluded with some reference to the work of the Dental Board in respect of education and discipline. As to the future, he expressed himself uncertain whether the numbers entering the dental profession were sufficient to provide for the growing needs of an increasing population or for the inevitable wastage from the *Register*. This latter would rapidly increase during the next twenty or thirty years, for of the 14,000 dentists on the *Register* no fewer than 40 per cent. were "Dentists 1921" who would not be replaced. It seemed clear, therefore, that there was a good prospect of a successful career for all students studying dentistry at the present time.

NEW INSTITUTE OF MEDICINE AT GLASGOW

THE GARDINER GIFT

With the opening on September 28 of the new Gardiner Institute of Medicine a fresh chapter has begun in the history of medicine at Glasgow. As Professor T. R. Elliott said at the opening ceremony, no medical school could retain its greatness unless, in addition to the duty of training practitioners, it sought also "to nourish those who had the zest for research in medical science." Sir Daniel Stevenson, Chancellor of the University, who presided at the ceremony, said that Sir Frederick Gardiner and his brother, Mr. W. G. Gardiner, were great benefactors of Glasgow University, especially on the medical side, and when new accommodation for the department of medicine was found necessary some two years ago it was the immediate and generous help of Sir Frederick and the trustees of his brother that had made the new Institute possible.

"Unit" Laboratory System

Professor J. W. McNee described the Gardiner Institute, which is fortunate in its site in that it leads off directly from the wards under the care of the Regius Professor of Medicine at the Western Infirmary, Glasgow. There are three floors. The third, or top, floor consists of a complete clinical unit, with separate rooms for patients, a complete dietetic kitchen (which will also be used for training dietitians), and full nursing facilities. Several laboratories are arranged at one end, but they are equipped in such a way as to allow of their easy conversion into bedrooms if necessary. The second or middle floor contains the three main laboratories, one equipped for all general methods of clinical research, one for chemical work, and one for physiological work. The laboratory equipment, supplied by Messrs. Baird and Tatlock of London, is on the new "unit" system. All the drainage, water, gas, and electrical supplies run in easily accessible but covered channels below the floor, and the laboratory benches, made up in short lengths or "units," are only lightly fixed to the walls so that they can be readily moved and connected elsewhere to the drainage and other services. The disposition of the equipment can thus be altered to suit new types of work with a minimum of expense. The ground floor is divided into two parts. On one side is the library and the professor's suite of rooms, consisting of a secretary's room, office, and combined consulting room and laboratory. There is an arrangement whereby the professor is allowed to see private patients in his own department, not only saving his time but also ensuring that he has all his equipment around him. On the other side is a small but complete out-patient department, opening on to the main out-patient entrance of the hospital. Here patients who have been resident in the main wards or in the top floor of the Institute will be "followed up" from time to time. This is an important facility allowing complete and continued survey of patients and their diseases with all equipment at hand. A small record office completes this out-patient department.

The Highest Aim of a University Faculty

In his concluding remarks Professor Elliott said that despite our skill in clinical practice and our possession of leaders of world-wide renown in physiology, pathology, and biochemistry, Scotland and England had been regrettably behind other countries in bringing these ancillary sciences into close co-operation with medicine. The practical skill of British doctors in the care of individual casualties was surpassed by none, but in the great war they had shown themselves sometimes unable to help in the general answers to new problems that arose. Since the war many young physicians and surgeons had spent a period of training abroad. They were not attracted to

A. R. Lozano (*Rinascenza med.*, 1938, 15, 548) reports that among 1,752 infants under 1 year admitted to the Municipal Institute in Madrid there were 155 subjects of habitual vomiting, of whom twenty-seven had undoubtedly or very probable and ten probable syphilis. As, however, the proportion of cases of congenital syphilis in subjects of habitual vomiting is not higher than 25 per cent., syphilis cannot be regarded as the only or as the most frequent cause of this condition.

the glamour of seeing the laboratories where insulin was discovered or the men who had found out the life-saving treatment of pernicious anaemia. They sought an experience of the system which had produced these wonderful gains for medicine. That system did differ from ours—though it had ceased to differ in London, Oxford, Cambridge, Edinburgh, and Aberdeen, and henceforward would cease to differ in Glasgow—in this point: that the study of medicine had been brought under the influence of that spirit of accurate scientific inquiry which was the highest aim known in a university faculty.

The opening ceremony was performed by Lady Gardiner, who wished Professor McNee and his assistants every success in the work to which they were so devoted. She said that the inspiration in making this gift was due to Sir Robert Muir, to whom her husband had always turned when he wished to do anything for the University. Among others present were the Principal of the University, Sir Hector Hetherington, Sir Robert Muir, Sir Henry Mehan, Sir George Mitchell, Dr. John Henderson, and Dr. D. J. Mackintosh.

Local News

SOUTH AFRICA

Health of Rand Miners

The report for 1937 of the Central Mining—Rand Mines Group—Health Department reflects credit on its able chief medical officer, Dr. A. J. Orenstein, and his staff. The organization now includes thirteen full-time medical officers, one part-time medical officer, and one research medical officer. During the year under review the mortality rate for diseases reached the record low level of 6.82 per 1,000. The morbidity rate for accidents due to employment, 226.18 per 1,000, is the lowest figure in the records of the group. Accidents not arising out of employment are stated to have increased again. It is hoped, however, that the removal of one of the worst slum areas, where illicit liquor selling was rife, and the building of municipal beer halls, where natives can obtain Kaffir beer, will have a beneficial effect. With regard to pneumonia, which constitutes a serious problem for the health authorities, the collected data after three years' inoculations with the "community anti-pneumonia vaccine" from the South African Institute for Medical Research were submitted for analysis to J. P. Dalton, Professor of Mathematics at the University of the Witwatersrand. His analysis, with a most interesting series of tables and graphs, is included in the report. The conclusion is obvious that, in the present state of medical knowledge, prophylactic inoculation against pneumonia cannot be relied upon to reduce markedly the incidence of the disease. Since it has been found, as a result of twenty-three years' experience, that the incidence of pneumonia almost always shows an upward trend during the cold months, the collaboration of the Government Meteorological Division was secured with a view to determining which of the meteorological phenomena, if any, played the dominant role. It appeared that pneumonia was most prevalent during the months of highest wind velocity, least rainfall, and lowest temperature. The curve of wind velocity corresponded most closely with the curve of the incidence of pneumonia. It would seem, therefore, that protection of the individual from the effects of the chilling winds is a matter of importance. To this end warm jackets have been issued to the natives, and shelters have been provided at the shaft heads on some of the mines. The report stresses the importance of these shelters as a preventive measure, and suggests that they should be provided at all shafts, that they should be adequate in size, and so constructed as to keep out wind and cold effectively.

ENGLAND AND WALES

Leeds Medical School: Retirement of Vice-Chancellor

Sir James Baillie, who has been Vice-Chancellor of Leeds University since 1924—a post to which he came from the professorship of moral philosophy at Aberdeen—retired at the end of September, and at the graduation ceremony held in the Medical School on September 23 occasion was taken to express to him in the name of the Medical Faculty the sense of gratitude he had evoked for his constant interest and help in medical education in the capital of the West Riding. In a brief farewell address Sir James Baillie offered to his colleagues on the medical staff his warm good wishes for their future and for the prosperity of the medical school. He would always retain, he said, the happiest memories of the various occasions on which he had been associated with the work of the several departments and of the loyal support which the staff had always given him in his efforts on the school's behalf. "No sphere of the University's activities has been to me of greater interest, no development in the University in recent years has afforded me greater pleasure and satisfaction than that of the Medical School; for in certain significant respects I regard the Medical Faculty as the most important and the most difficult domain of pure and applied science in the whole range of the academic curriculum." He went on to say that the high standing of the school in the eyes of the medical world was publicly acknowledged on the occasion of the centenary of the foundation in 1931. With the ampler and more appropriate accommodation secured in recent years, with the enlarged scientific staff and the greater financial resources, the school had entered upon a career of extended service to the vitally important cause of medicine. There was much still to be done, but the future, he was sure, was safe in the hands of those he was addressing to provide a new inheritance of knowledge for their successors and to give an added distinction to the University. He also expressed the hope that the growing community of interest between the members of the Medical Faculty and the whole University would be strengthened and increased as the years went on, for it was one and the same spirit of knowledge animating the whole life of the University which was the inspiration of every part. The Dean of the Faculty (Mr. Harold Collinson) expressed the general regret at Sir James Baillie's departure. By his retirement he said that the University lost the services of a man who had devoted himself heart and soul to the furtherance of its interests, the increase of its activities, and the cause of University education in the North of England. During his reign as Vice-Chancellor the development of the University had been phenomenal. In the department of medicine he had invariably encouraged and supported any suggestion for improvements in teaching and facilities for research, and in certain instances had initiated them himself. Any scheme suggested by the department had always been received by him in a sympathetic and understanding manner, and his wise counsels had been of the utmost assistance. As the head of the University in the wider field of public life, his dignity and eloquence had everywhere maintained and enhanced its prestige and influence.

King Edward VII Welsh National Memorial

The opening and dedication of the Hall of Nations at Cathays Park, the civic centre of Cardiff, will take place on November 23. The hall has been built by Lord Davies at a cost of £62,000, and apart from its work in connexion with the League of Nations Union will become the headquarters of the King Edward VII Welsh National Memorial Association, the organization which has done such valuable work in Wales in the prevention and treatment of tuberculosis, and of which Lord Davies is president. It will be remembered that Lord (then Mr. David) Davies and his sisters were responsible for founding this association in 1910. Following the Insurance Act of 1911 the functions of the association were extended to

include the administration of sanatorium benefit, then in 1921 the seventeen county and county borough councils of Wales delegated to the Memorial Association their obligations under the Public Health (Tuberculosis) Act of 1921, so that now, while the Association retains its voluntary character, it has become a semi-public service representing all the contributory authorities in the Principality. So comprehensive is its machinery, that with the numerous hospitals, sanatoria, and clinics administered by it, maintenance expenditure alone amounts to nearly £300,000 a year.

Chadwick Lectures

The following Chadwick Public Lectures have been arranged on Tuesdays and Thursdays at 5.30 p.m.: October 11, at Niblett Hall, 3, King's Bench Walk North, Inner Temple, E.C., Mr. Roland Burrows, K.C., "The Development of Public Health Law during the Past Fifty Years"; October 27, at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., Dr. Norman Macfadyen, "The Evils of the Congestion of Population and the Way Out"; November 8, at the Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, W., Sir Stanley Woodward, "The Rise and Fall of Certain Diseases Concurrent with the Progress of Sanitation and Hygiene"; November 24, at the Royal Institute of British Architects, 66, Portland Place, W., Malcolm Morris Memorial Lecture by Mr. W. W. Wakefield, "Playing Fields and the National Fitness Movement"; December 13, at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., Dr. Leonard Colebrook, "The Control of Puerperal Fever."

Correspondence

Medical Man-power in War

SIR.—The authorities have drawn up various schemes for utilizing the services of the medical profession in time of war. While I appreciate the good points of these schemes, and have no wish to be unduly critical, yet such schemes are drawn up largely as the result of experience of the last war and do not provide for certain obvious differences in modern warfare. I would therefore invite attention to the following points:

1. Assuming that no expeditionary force is dispatched, at any rate to begin with, the Territorial base hospitals will be standing idle if only used for military wounded. Yet these hospitals will be staffed by men receiving pay and in many cases busily employed in private practice.
2. In London and similar places there may be heavy civilian casualties as the result of air raids—which were only in their elementary stages in the last war. The voluntary hospitals will be flooded with such cases. If the honorary staff deal with these cases in a really conscientious manner they will, immediately after an air raid, have little time for their private practices. Are they to carry out this work on an eleemosynary basis? If so, it seems rather hard on these honorary staffs, especially in view of 1.
3. In areas not actually raided but receiving the evacuated sick of London a similar state of affairs to 2 will exist.
4. It is hoped that efforts will be made to use the medical profession in an economical manner. Should Territorial divisions be mobilized and held for any time more or less idle in camps in England, I would suggest that, except for a small nucleus, the regimental medical officers and officers of field ambulances might be seconded for service in dealing with air raid casualties, or other work of national importance, rather than sitting about in camps awaiting events.
5. I would also remind readers of the gross waste of medical services in the last war in the hope that such waste may be prevented in the next. I will content myself with two examples of such waste. In the Eastbourne R.A.M.C. train-

ing centre a medical officer was employed as a riding instructor! In 1917, when there was a real dearth of doctors for dealing with civilian sick in England, I was detached from a field ambulance in France and put in charge of a laundry on the outskirts of Bethune!

I am sure that all of us are ready and willing to do our bit in a national emergency, but such eagerness would be increased and the sacrifices involved borne more cheerfully if we were convinced that the burden was evenly and sensibly distributed.—I am, etc.,

H. J. MCCURRICH, M.S., F.R.C.S.

Hove, Sussex, Sept. 29.

* It will be noted that this letter was written before agreement was reached at Munich. We publish it because the plans which were then incomplete will have to be completed in case of future emergency, for reasons set out in a leading article at p. 749 and in the opening pages of this week's *Supplement*.—ED., B.M.J.

Organization of Trained Nurses in Emergency

SIR.—The British Medical Association, at the request of H.M. Government, has compiled a register of doctors; and from the same source a request has been made that the College of Nursing should organize similar machinery for nurses. The object is to set up a reserve composed of State-registered and certificated nurses, having no other obligations, who would be available in time of national emergency to augment the present health services. It is felt that throughout the country there must be many who, either married or retired from active service, would be anxious to link up with some organization through which their skill could be utilized. Many hundreds of extra nurses will be required to supplement the staff of hospitals, district nursing associations, and other institutions, and I would ask every nurse coming under the categories mentioned above to get in touch, immediately with the headquarters of the College of Nursing, 14, Henrietta Place, London, W.1, or any of its local branches (lists of these may be obtained from headquarters). Nurses have ever been ready to serve their country, and I feel assured that this appeal will meet with a ready response.—I am, etc.,

FRANCES G. GOODALL, S.R.N.,
Secretary, College of Nursing

London, W.1, Sept. 29.

Social Pathology

SIR.—In view of the tragic happenings in the world and the series of convulsive crises through which civilization is passing, it seems strange that our profession, so used to dealing with disease both physical and mental, has no theory of the pathology of society to offer. Is it not obvious that a civilization which within these last few days has been on the verge of suicide must be in a diseased condition? And if so, should not its malady be susceptible of scientific study, like the diseases of an organism? I hope some readers of the *Journal* will agree with me that the medical profession, above all others, is that qualified to deal with social pathology, and that it is indeed its duty to study it. Why then does it not do so? In the hope of stimulating interest in this matter I venture to advance one preliminary conclusion at which I have myself arrived.

In view of the constant accretion of social services in all countries of Western civilization, how is it that this civilization is becoming not more but less healthy, as evidenced by its recent tendency to disintegrate altogether? I suggest that in multiplying the social services we have been merely treating symptoms, and that, our attention being thereby increasingly engaged, we have been

and more neglecting the underlying disease. In other words, civilization is breaking up precisely because it has been deserted by the "qualified practitioners" and handed over entirely to the frank and self-confessed empiricism of politics.

Do any readers agree with me that the doctors, by virtue of their peculiar experience, are the very people who should study social pathology and who would be most likely to discover its laws and so lay the foundations of rational treatment and prophylaxis? The Westminster and Whitehalls in all countries have made a sad mess of the whole business. What about the humble general practitioner stepping in now? If this letter awakens any kind of response I should like to submit one or two further generalizations which I think might prove of use.—I am, etc.,

North Queensferry, Fife, Sept. 30.

A. J. BROCK.

The Prognosis of Anxiety States

SIR,—The article by Dr. Arthur Harris in the *Journal* of September 24 (p. 649) is a valuable and valiant attempt to assess the imponderable. It is valuable since many people would deny the right of medical psychology to call itself a science precisely because it does not lend itself to exact measurements, and in spite of the marked change in the attitude of the profession during the past ten years or so psychology still stands in need of all the backing it can get, to win the approval of those whose good fortune it is to have to deal only with disorders which have as a basis a demonstrable lesion.

The method of grading adopted by Dr. Harris is certainly useful and practical so far as it goes, but a neurosis is such an individual condition that it is impossible to apply any general standard of measurement. It represents the reaction of the individual to his environment, and the environment is something far more subtle than the financial or family worries which Dr. Harris mentions. My own experience is leading me to the conclusion that, whereas fear is the reaction of the organism to anything which threatens its physical fitness, anxiety is the response to a threat to the integrity of the personality. There is the adolescent whose urge to fulfil himself comes up against the restrictions and taboos of family and society. There is the husband or wife who has been reduced to a cipher and robbed of all initiative through being constantly exposed to the assertiveness of the other partner. There is the girl whose devotion to a parent is robbing her of her birthright of marriage, and the married man or woman whose urge to parenthood is being thwarted by the selfish caution of the other. The prognosis of a neurosis depends primarily upon what I should call "the worth-whileness" of the patient—that is, the willingness of the patient to contribute to life—and, secondly, upon the degree to which those in close touch can be brought to co-operate. I cannot see that we shall ever be able to sum up such factors in a formula.—I am, etc.,

Birmingham, Oct. 1.

R. MACDONALD LADELL.

Allergy and Immunity

SIR,—In your review of the recent important researches on allergy and immunity in ocular tuberculosis carried out by the staff of the Wilmer Ophthalmological Institute (*Journal*, September 17, p. 627) you indicate the support this work lends to the contention of Rich and his associates that allergy and immunity are two distinct processes.

It is unnecessary to detail the controversies that have developed in the past in order to emphasize the sharp

differentiation of current opinions into the two opposed schools—the first teaching that the allergic state is an essential part of the immunological mechanism accompanying recovery from infection, and the second which adopts the contrary view on the grounds that allergy and immunity may exist independently, and considers that their association in many natural infections is entirely fortuitous. The latter view has met with increasing acceptance during the past few years, due chiefly to the researches of Rich and his co-workers.

It is my considered belief that much of this conflict of opinion is due to a failure to realize (1) that there is more than one form of bacterial allergy, as there undoubtedly is of immunity, and that any given relation between one form of allergy and immunity does not necessarily hold for the other forms; and (2) the impropriety of attempting to formulate generalizations from the study of a restricted aspect of the subject.

Recently I have attempted to analyse the relation between immunity and allergy in rabbits with reference to the pneumococci and their products, and also to correlate my results with those of other workers (*J. Path. Bact.*, 1935, 41, 491; *ibid.*, 1937, 45, 257). In brief, rabbits were treated with pneumococcal vaccines by various routes and their skin reactions to (1) SSS (specific carbohydrate), (2) NP (nucleoprotein), and (3) intact organisms, together with their serum agglutinins, anaphylactic and protective antibodies, and degree of active immunity, determined by appropriate methods. The conclusions were as follows. The three types of cutaneous allergy—namely, to SSS, NP, and intact organisms—are immunologically independent.

(1) *Allergy to the SSS* is closely related to type-specific immunity and to SSS anaphylaxis, and it was concluded that these three forms of immunological reaction are probably expressions of the same basic mechanism—namely, the union of the type-specific antigen or its haptene with the homologous antibody, and that the apparent differences are only quantitative variations of the common mechanism: "type-specific immunity" when the antibodies react *in vivo* with small amounts of antigen in the test dose of living organisms and render the latter vulnerable by the host; "anaphylaxis" when the reaction takes place between the same antibodies and the antigen haptene in the tissue cells; and "allergy" when it occurs in the skin. (2) *Allergy to NP* is dependent on the presence of circulating NP antibodies, is unrelated to type and species immunity, and is essentially an antigen-antibody reaction between the NP and its antibody. (3) *Allergy to the intact organisms* is independent of type and species immunity and is not even type or species specific, being elicited by *Streptococcus viridans*. It appears to depend on an increased reactivity of the tissue cells as opposed to an antigen-antibody reaction, and the allergic state is not capable of passive transfer to normal animals by the injection of serum from the allergic individual, in contradistinction to the states of allergy to the SSS and NP, which are capable of such transfer since they depend on the presence of antibodies of the "circulating" type.

Thus, while the deductions of the Baltimore school may afford a true representation of the problem with reference to tuberculosis, the data obtained from the study of the pneumococcus makes it clear that no broad generalization on the relation of bacterial "allergy" to "immunity" is possible in view of the existence of different forms of bacterial allergy bearing different relations to anti-bacterial immunity.—I am, etc.,

DAVID HARLEY.

Academic versus Clinical Anatomy

SIR,—It seems that the tables have been turned upon the academic anatomists who are for ever hiding behind the barricade of their changing terminology. The clinician has been to blame for increasing the students' tasks by talking in pre-war terms. It comes as somewhat of a surprise to find new and revised editions of standard anatomical textbooks enlarging upon the primitive streak and yet completely ignoring the works of clinical research in the more coarse matters of anatomy. It is seven years since the Medical Research Council published the work of Dr. Ormond Beadle on the intervertebral disks. It was shown conclusively by this author, working under Professor Schmorl, that the epiphyseal plates of the vertebral bodies ossified from several peripheral centres placed in the radial ridges of the cartilage and occurring in numbers from two to seventeen according to the level of the vertebra. This is taken as a basis to the understanding of some of the diseases of the adolescent spine. Reference is made to this multicentric ossification in one standard orthopaedic textbook at least (by Mercer, 1936; Arnold). The conclusions are accepted, I believe, by the great body of orthopaedic surgeons and radiologists. In fact, in a recent edition (*Surface and Radiological Anatomy*, by Appleton, Hamilton, and Tchaperoff; Heffer, 1938) a fine radiograph of an adolescent spine is shown exhibiting these centres of ossification at the anterior edges of the epiphyses. In spite of this, the latest edition of such a famous anatomical textbook as *Gray's Anatomy* boldly states and illustrates that the plate has one centre of ossification.

Maybe this is a silly pretext for a letter, but it does show how far apart the academic and applied aspects of one subject can be divorced—further, indeed, than the mere difference of terms.—I am, etc.,

London, S.W.1, Sept. 27.

D. F. ELLISON NASH.

George III and his Physicians

SIR,—I was greatly interested in Dr. Walter R. Bett's notes (September 24, p. 664) on the mental illness of George III and his reference to two of the great pioneers in the more humane treatment of the insane—Pinel and W. Tuke, the latter of whom founded the York Retreat in 1796. At the moment I am writing a short history of the six medical and lay pioneers in this great work, covering the years from 1784 to 1844, years of great and tragic interest. In an excellent account of the York Retreat written by Mr. Harold Hart (at one time steward of that great institution) and edited by the present medical superintendent, Dr. Neil McLeod, mention is made of the Bristol Quaker, Dr. Edward Long Fox, who in 1795 owned a private asylum at Cleve, near Downend, which in the next year was removed to Brislington House. He was requested to meet in consultation the physicians then attending George III with the view that His Majesty should be a resident patient at Brislington House. He declined both honours. His descendant Dr. Edward Long Fox of Clifton was a valued friend of mine through my early years of medical practice. I had been his clinical clerk when he was physician to the Royal Infirmary, Bristol, and I frequently called him into consultations during my twelve years of general practice. He was President of the British Medical Association in 1894 when the Annual Meeting was held at Bristol. He was always proud to speak to me about his ancestor of Brislington House, and delighted to inform me that he was the first medical super-

intendent of a private asylum to introduce religious services in accord with the Church of England for his patients.

George III's mental illness was remarkable for two reasons: one the length of his illness—fifty-two years; secondly, the very clear lucid intervals he had during those years. I fear he was subjected to unkind treatment, and history tells us that not only was he in mechanical restraint but on two occasions was knocked down "flat as a pancake" by an ill-tempered and cruel attendant. It was at this time that Phillipe Pinel in 1792, in spite of much opposition and at danger to his life, released fifty-five lunatics at the Bicêtre, Paris, from chains and manacles, many of them having been so restrained for years and lodged in dungeons without a glimpse of the blue sky or the healing rays of the sun. This great work of humanity can never be forgotten, and no one can rob Phillipe Pinel of the honour of being the first pioneer of the more humane treatment of mental diseases. His name will be ever blessed by all interested in the welfare of the insane.—I am, etc.,

Bournemouth, Sept. 26.

LIONEL A. WEATHERLY, M.D.

SIR,—May I add a few words to the interesting account given in the *Journal* of September 24 (p. 664) on the many illnesses of George III, as I have what is probably a unique contemporary document connected with Dr. Willis and his high-handed treatment of the medical men in charge of the King.

Dr. F. Willis came to Kew early in December, 1788, and obtained from the Queen permission to treat the King in the same manner as he practised on his private patients. On obtaining leave he immediately dismissed all the attendants and put in his own. He then placed a notice on the "outer door" as follows:

No one except the Pages are to be suffer'd at any time to go into his Majesty's room unless they are introduced by, or have leave from one of the Dr. Willis's.

Jan. 2, 1789.

I have a copy of this order copied by my great-great-grandfather, Dr. Henry Revell Reynolds, who was one of the King's physicians and in constant attendance. This order was copied on the back of a note that runs:

My dear Doct^r,

His R.H. the P. of Wales commands me to inform you that a motion will be made in the House of Lords that the King's Physicians may be examined at the bar of the House

yrs sincerely G. BAKER

Jermyn Street.

4 Jan. 1789.

I have little doubt that he wrote on this letter because it happened to be the only piece of paper he had with him.

In evidence before the Lords Dr. Willis tried to throw the onus of this order on the Lord Chancellor. Dr. Reynolds stated in his evidence that he saw the original order on the 4th, a Sunday. "I took a copy of it," he said, though as a matter of policy he had taken no note of it.—I am, etc.,

Oxford, Sept. 26.

BERTRAM M. H. ROGERS

Parental Whole Blood as Measles Prophylactic

SIR,—May I endorse Dr. T. D. Culbert's recommendation (*Journal*, October 1, p. 705) to use adult whole blood in the prophylaxis of measles in preference to serum or immune globulin. I have repeatedly obtained complete protection with 15 to 20 c.cm. injected during the first week after exposure. There are no reactions. The procedure is simplified in family practice if the blood is citrated to prevent clotting. A 20 c.cm. syringe is charged with 2 c.cm. of isotonic (3.8 per cent.) sodium citrate.

solution from sterile ampoule or rubber-capped bottle and then filled with parental blood. This can now be taken into another room and without haste injected into the child's buttock. Experience on large numbers is still required, and should enable us to obtain the desired grade of attenuation.—I am, etc.,

London, W.1, Oct. 1.

F. E. LOEWY.

Maternity "Flying Squad"

SIR,—In the light of thirty years' experience of semi-rural practice I suggest that a maternity flying squad is unnecessary. Given really careful ante-natal work two general practitioners, if one is well experienced, can do all that may usefully be done in a cottage. Surely cases of eclampsia should always be moved, and if Caesarean section becomes unexpectedly necessary it is quicker and better to move the patient straight from ambulance to theatre. The one thing the experienced general practitioner does want is to have at immediate call a transfusion service, since excessive haemorrhage has often taken place before even he arrives.—I am, etc.,

Kington, Herefordshire, Sept. 27.

G. W. DRYLAND.

Vitamin C in Milk

SIR,—In answer to Dr. J. H. Lloyd's query in the *Journal* of September 10 (p. 597), dark amber or red glass bottles would be suitable to protect vitamin C from destruction by light, but there would obviously be great economic (and aesthetic) difficulties in changing the current type of milk bottle. Amber bottles have been on the market and were disliked by the consumer. Cartons, which are unobjectionable from a bacteriological point of view when properly dealt with, are definitely better than clear glass bottles regarding the stability of vitamin C. It is, however, widely believed that at present they could not compete on a large scale with glass bottles on account of cost.—I am, etc.,

National Institute for Research in Dairying,
Shinfield, Sept. 27.

S. K. KON.

Ménière's Disease: Personal Experience

SIR,—A sufferer from Ménière's disease, I was interested in Dr. W. Russell Brain's paper on vertigo in your issue of September 17 (p. 605), and also the one by Dr. Wright published in the *Journal* of March 26 (p. 668), and am tempted to record a personal experience.

About eight years ago I had my first definite attack—faintness, giddiness, inability to stand, nausea, vomiting, and profuse perspiration. After a night's rest I was normal again. Thereafter I had many attacks at varying intervals of a few months to a few weeks, but gradually lessening in severity. Many of the attacks came on just as I was sitting down to a meal. One end of the table would appear to sink to the floor, always on the right side; I would grip the edge of the table and forthwith fall to the floor on the left side; then would follow the usual symptoms—faintness, perspiration, nausea, and sickness, and, after a sleep, recovery.

I must confess that I had no great faith in any medicinal treatment, and did not care to submit to any operative procedure. However, I read an article by Dr. Ramsbottom of Manchester University in vol. ii of *Modern Technique in Treatment* (1926) in which he recommended small doses of quinine with or without bromides. His prescription was: quinin. sulph. $\frac{1}{2}$ grain, acid, hydrobrom. dil. 15 minims, tinct. aurant. 20 minims, water to half an ounce. I took this mixture with the addition of $7\frac{1}{2}$ grains of potassium bromide twice daily for several years, and, indeed, am still taking it rather irregularly.

From various sources I gathered useful hints, such as reducing fluid intake to a minimum, cutting down tobacco to one ounce a week, no alcohol except an occasional glass of sherry. I also had a carious incisor tooth and two or three roots extracted.

It is gratifying to me to find that the two doctors I have named, Dr. Wright and Dr. Brain, approve of the line of treatment I adopted, the former especially stressing the importance of looking for a septic focus.

And now the sequel. I have not had an acute attack for three years. I am quite deaf on the right side and the hearing is not too good on the left, but my general health is good.—I am, etc.,

Boole, Liverpool, September 23.

JOSEPH WALKER.

Tuberculosis Dispensaries or Chest Clinics?

SIR,—As the existence of tuberculosis dispensaries has been widespread for twenty-five years, is it not rather late to worry about the name? In so far as dispensaries have effectively carried out one of their primary functions—namely, education of the public—they ought through personal instruction and their work as treatment centres to have spread abroad two well-established facts. (1) Tuberculosis, if diagnosed reasonably early and properly treated, can frequently be arrested or cured. (2) Many persons with unsuspected chronic phthisis carry out their daily tasks more or less efficiently for years, and only break down as the result of strain or some intercurrent illness in middle life.

Where new buildings are concerned there may be something to be said for dropping the word "tuberculosis," but in the case of old-established dispensaries the arguments are less valid; the buildings are, or ought to be, known for what they are. Recently at my five dispensaries this has actually been done, and we have not so far noticed any change in the attendance or demeanour of patients.

Much depends upon the knowledge and attitude of the general practitioner. By wise and tactful handling suspects can often be induced to visit dispensaries "to make sure that they are all right," as tests and examinations are nowadays general. A matter-of-fact manner combined with a simple statement as to the present improved facilities for diagnosis and treatment can do much to allay the fears of the timid. Indeed, candour is the surest way to gain or retain confidence.—I am, etc.,

Leigh, Lancs, Oct. 1.

G. JESSEL.

SIR,—Judging by the letters of Dr. G. Gregory Kayne in the *Journal* of September 17 (p. 634) and of Dr. E. P. Edmonds (October 1, p. 722), I do not think that they appreciate Dr. P. Ellman's main point sufficiently, and that is that by calling the dispensary a chest clinic more patients will be willing to attend for examination.

By this method, in my opinion, more early cases will be seen. It is much better for the patient, psychologically, to be told by his doctor that in order to complete his examination he is to be sent to the chest clinic, where he will be x-rayed and his sputum examined, than to tell him that he is going to a tuberculosis dispensary.

In my own practice in East Ham, where, as Dr. Ellman says, the name of chest clinic is given to the "dispensary," I have rarely had a patient refuse to attend, and my general impression is that patients are only too pleased to find that all investigations are being carried out.—I am, etc.,

London, E.6, Oct. 1.

C. RUTTER.

* * This correspondence is now closed.—ED., *B.M.J.*

Obituary

L. S. T. BURRELL, M.D., F.R.C.P.,

Physician to the Brompton Hospital and to the Royal Free Hospital

We regret to announce the death at the age of 55 of Dr. Lancelot Stephen Topham Burrell on September 28.

Dr. Burrell was educated at Eton and Trinity College, Cambridge, and completed his medical studies at St. Thomas's Hospital. He qualified for the practice of medicine by taking the Conjoint Diploma in 1908, in the same year as he proceeded to the M.A. degree at Cambridge. Two years later he took the M.B., B.Ch., and in 1913 the M.D. He was elected Fellow of the Royal College of Physicians in 1924. After acting as medical registrar and

resident assistant physician at St. Thomas's, his first important post outside his hospital was his appointment in 1913 to the staff as physician to out-patients at the Brompton Hospital. This appointment proved a most happy one for both the hospital and himself, for it gave him the opportunity for adding special experience to a general knowledge of clinical medicine. That special experience and opportunity have left their mark on the treatment of pulmonary tuberculosis. At a time when

a few tentative trials were being made in this country in the first form of collapse therapy—namely, by artificial pneumothorax—Burrell's inquiring mind determined him to make an extensive research into its clinical possibilities. Starting this work soon after his election to the staff it is probable that the first induction of a pneumothorax at the hospital was done by him, and not even then without some misgivings as to its desirability being entertained by his more senior colleagues. Artificial pneumothorax treatment has progressively and ever increasingly gone ahead at the hospital from this small beginning, and special clinics for "refills" are needed daily for the out-patients requiring it while continuing, in very many cases, at their work. It would be justifiable to claim that his was recognized as the most authoritative opinion on artificial pneumothorax therapy in pulmonary tuberculosis in this and any other country. The Brompton Hospital will ever be the better for having acquired his services.

Dr. Burrell's rising reputation as a specialist in diseases of the lung led to his appointments on the medical staffs of Midhurst, Ventnor, and Benenden Sanatoria, and of Papworth Village Settlement. Then at the age of 44 he received the rare distinction of an invitation to accept the vacant post of a senior physician in one of the teaching hospitals of London and one with which he had never before been associated. His appointment of physician to the Royal Free Hospital was made in 1927, and he was its senior physician at the time of his early death. He always maintained what he regarded as a necessary balance between his special work on diseases of the lung—an associated office in general medicine. Before going to the Royal Free he had carried this out for some years as a physician on the staff of the West London Hospital. The pressure of

his work caused him to relinquish this appointment when he transferred to the Royal Free. He was also Physician to the Lord Mayor Treloar Cripples' Hospital. Burrell was Editor of the *British Journal of Tuberculosis*, co-author of a clear and concise textbook, *Diseases of the Chest*, published in 1930 and still the best of its kind. His contributions to discussions on almost any of the pulmonary diseases were numerous, whether at a congress or at ordinary medical societies. This was perhaps at the penalty of fame and a well-known kindly nature.

To his contemporaries Burrell was always considerate, courteous, and tolerant, and no junior could wish for a more friendly and helpful senior. He was incapable of attributing an unworthy motive to anyone, and was widely regarded with real affection. Lenient to an unusual degree, he could be firm when a matter of principle was involved.

In no way was he more fortunate or more to be envied than in the happiness of his family life with his wife and two daughters. He married Ruth, eldest daughter of Dr. R. Rose Clarke. It was ever a joy to his friends to see him so serenely happy in his home.

Burrell was vice-president of the Section of Tuberculosis at the Annual Meeting of the British Medical Association in Winnipeg in 1930, and again at the Centenary Meeting in London six years ago.

Sir Arthur MacNalty writes:

For nearly thirty years Lancelot Burrell and I have been friends. I first knew him as a slight, good-looking boy when I was resident medical officer at Brompton Hospital and he came there as a house-physician. Eton, Cambridge, and St. Thomas's Hospital had trained and developed his intellectual powers, and of these schools there can have been few better products. Even in those early days Lancelot Burrell was marked for high place in his chosen profession. Later on we had many contacts, both professional and social. He served with me on the Tuberculosis Committee of the Medical Research Council, where his wide clinical experience and knowledge were of great assistance. Together we planned and wrote in 1922 a report on artificial pneumothorax, published in the Medical Research Council Report Series which I have reason to believe stimulated interest in and led to more general adoption of that form of treatment in pulmonary tuberculosis. The major share of that contribution belongs to Burrell. His writings on tuberculosis always displayed knowledge, interest, and original observation, while in consultation on a case his skill in diagnosis and selection of the best treatment for the individual patient betokened the competent physician. Burrell always worked at high pressure. He spent his great gifts freely for the good of others. He made no enemies, but countless friends. I know of a thousand acts of kindness which he did without fee or reward. He endured and faced a distressing and protracted illness in his last days with wonderful resignation and indomitable courage. Our deep sympathy goes out to his widow and family.

Dr. Halliday Sutherland writes:

The untimely death of Dr. L. S. T. Burrell is a great loss to the anti-tuberculosis campaign. Yet we should be grateful that he accomplished so much during his five years of life. As a medical student he had learned the limited outlook on the aetiology, prevention, and treatment of tuberculosis, best summarized in that now obsolete word "phthisis." All that has disappeared. Radiography has now its place in diagnosis; artificial pneumothorax and other surgical methods have their place in treatment. To Burrell more than to any other man in London

reason of his work at Brompton Hospital, should we be grateful that these methods, with the exception of major surgical operations on the chest, are now rightly regarded as coming within the province of physicians who specialize in tuberculosis. At one time there was a danger that these methods of diagnosis and of treatment might be claimed by other branches of medicine, and that the expert in tuberculosis would become an *entrepreneur*. By his colleagues on the Medical Committee of the Queen Alexandra Sanatorium Fund he is remembered as a most kindly man, very tolerant, and always willing to consider the opinions of others. Before his long and distressing illness, one of his last remarks to myself was this—"Let's meet and have a talk about tuberculin." *Ave atque Vale.*

[The photograph reproduced is by Elliot and Fry, Ltd.]

C. G. RUSS WOOD, F.R.C.S.

Consulting Ophthalmic Surgeon, Royal Salop Infirmary

We regret to announce the sudden death on September 26 at the age of 69 of Cyril George Russ Wood, O.B.E. He was the only son of Mr. Cyril J. Wood of Bath. His medical studies were pursued at Bristol University, and he obtained the M.R.C.S., L.R.C.P. in 1892 and the F.R.C.S.Eng. in 1902. At first his main interests were devoted to the study of pathology, but shortly afterwards he came under the stimulating and inspiring influence of the late Mr. F. Richardson Cross, who turned his thoughts to ophthalmology and led to his appointments as honorary ophthalmic surgeon to Southport Infirmary and Southport Eye, Ear, and Throat Hospital. In 1900 he was appointed honorary surgeon to the Eye, Ear and Throat Hospital, Shrewsbury, and it is to his lasting credit that in the exceedingly full and busy life that followed he gained his Fellowship, though among other difficulties it involved a visit twice weekly to Birmingham University for the study of practical anatomy.

His devoted services to the hospital in Shrewsbury were the means of raising its status to a very high level, and his name soon became widely known and respected in Shropshire and Mid-Wales, not only as an ophthalmic surgeon but also as an otolaryngologist. He added to

his appointments those of honorary ophthalmic and aural surgeon to the Royal Salop Infirmary, the Shropshire Orthopaedic Hospital, Wrexham Infirmary, the Montgomery County Infirmary, and Much Wenlock and Broseley Hospitals, to all of which he held the position of honorary consulting ophthalmic surgeon at the time of his death. His connexion with the British Medical Association dates from 1892, and he was from 1900 to 1931 an active member of the Shropshire and Mid-Wales Branch, being elected president in 1925.

Since the institution of the Oxford Ophthalmological Congress in 1909 Mr. Russ Wood, as one of its founders, had always been one of its keenest and most active members. He was elected honorary secretary in 1928 and became Master in 1935. He served as president of the Midland Ophthalmological Society, being elected to deliver the Middlemore Lecture in 1927, and he was also a member of the general committee of the *British Journal*

of *Ophthalmology*. On his retirement from practice in Shrewsbury in 1931 he was elected assistant surgeon and pathologist to the Oxford Eye Hospital, and later consulting surgeon, while at the same time he became lecturer in the Oxford postgraduate course in ophthalmology and examiner in ophthalmology to Queen's University, Belfast.

Mr. Russ Wood had a very wide knowledge of the literature of his subject, and his contributions, though comparatively few, were essentially practical. Outside his professional work he had many interests. In his earlier life he was a keen amateur actor, was a great walker, and was never happier than when "doing something to the car." He was a reader and student of history; his conversation was always stimulating, revealing the wide range of his knowledge. In 1898 he married Fanny Mein, daughter of Dr. Charles Steele of Clifton, and had three daughters, to whom he was not only a father but a friend. To his wife's support and devotion he freely acknowledged much of his success, and from her death in 1935 he was never quite the same man again. He will perhaps be remembered best as a great organizer, a man of enormous industry and capacity, his work being characterized by soundness and good judgment. His personality attracted a wide circle of life-long friendships and his loss will be deplored by many.

Dr. HERBERT DEVAS EVERINGTON of Sanderstead, near Croydon, who was killed on September 23 in a motor accident at the age of 64, was a native of Dereham, Norfolk, and from Westminster School entered St. Bartholomew's Hospital, taking the English Conjoint diplomas and the M.B.Lond. in 1899. His early appointments included those of clinical assistant at St. Bartholomew's, house-surgeon at the Royal Free Hospital, and resident medical officer at the Royal Waterloo Hospital for Children and Women. During the war he served for a year as temporary lieutenant in the R.A.M.C. Dr. Everington had practised for many years at Sanderstead, and was a past-president of the Croydon Medical Society. He had been a member of the Croydon Division of the British Medical Association since 1902.

Dr. FREDERICK BOILEAU TREVES, O.B.E., who died on September 30, aged 58, was the son of the late William Treves, whom he succeeded in practice at Margate, and nephew of the late Sir Frederick Treves, the eminent London surgeon. He studied medicine at Caius College, Cambridge, taking his B.A. in 1901, and at St. Thomas's Hospital. He qualified with the English Conjoint diplomas in 1906, and took the M.B., B.Ch. degrees at Cambridge in 1909, after acting as clinical assistant in the throat department at St. Thomas's and house-surgeon to the West London Hospital. At Margate Dr. Treves became honorary surgeon to the Cottage Hospital and the Victoria Home for Children, and honorary surgeon to the Royal Sea Bathing Hospital. He served with distinction during the war, and reached the rank of lieutenant-colonel commanding the South-Eastern Mounted Brigade Field Ambulance. After the armistice he became medical referee for Margate under the Ministry of Pensions. He had been a member of the British Medical Association since 1908.

We regret to announce that Dr. HERBERT JOHN ROPER died from a cerebral haemorrhage while on holiday in Cornwall. Dr. Roper qualified M.R.C.S., L.R.C.P. in 1887, and he was in general practice in Leeds for forty-seven years. He studied medicine at Leeds, where he had a distinguished student career, obtaining medals in anatomy (senior and junior), materia medica, midwifery, surgery, and medicine. He won the Thorpe Prize for medicine and hygiene. During the war Roper acted as a civil surgeon to the 2nd Northern General Hospital. He was an examiner and a life member of the St. John Ambulance Association. He was a keen member of the British

The address by Sir StClair Thomson on "Lister at the College and Hospital," announced in this column in 6th of September 24 to be given on October 4, has been postponed until Tuesday, October 11, at 4 p.m.

Medical Notes in Parliament

Foreign Policy Debate: Air Raid Precautions

During the debate on the foreign situation in the House of Commons on October 4 Mr. ATTLEE urged that time should be given to discuss the whole question of air raid precautions, the extent to which they had been effective, and the extent to which the provisions were going to be continued. This question, he said, was interesting the mind of the country and the minds of members of the House, and he could see no reason why the House should propose to adjourn on Thursday, October 6. Mr. CHAMBERLAIN said he would consider what Mr. Attlee had said, and he would make a statement in the course of the day.

Mr. H. MORRISON said he did not think there was reason for general satisfaction with regard to the preparations for A.R.P. which were made by the Government.

Later Mr. CHAMBERLAIN said the debate on foreign policy would conclude on October 6. It was proposed that the House should then adjourn until November 1. Power would be given to the Speaker to call the House together at an earlier date if the public interest so required.

Mr. ATTLEE said that the Labour Party did not acquiesce in the adjournment of the House till November 1.

Sir THOMAS INSKIP said on October 4 that the test of last week had revealed grave defects in the national defence arrangements, and that both civil and military provisions would be improved. Steps had already been taken for that purpose.

Medical News

Queen Mary will open on October 21 the new Albert Dock Hospital established by the Seamen's Hospital Society. It contains sixty-four beds and a model fracture clinic and rehabilitation centre.

The Voluntary Hospitals Emergency Bed Service announces that a full twenty-four hours service, every day in the year, will be in operation as from October 8. Further particulars can be obtained from the secretary, 10, Old Jewry, E.C.2, telephone number Metropolitan 8781.

Lord Horder will deliver the inaugural address before the Edinburgh Philosophical Institution on Tuesday, October 11. His subject is "Medicine and Religion."

Under the auspices of the British Homoeopathic Association Dr. F. H. Bodman will give a lecture on "The Present-day Confirmation of the Homoeopathic Approach" in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole Street, W., on Thursday, October 13, at 5 p.m., with Sir John Weir in the chair.

The presidential address to the British Institute of Philosophy, entitled "Twenty Years After—A Survey," will be given by Viscount Samuel at University College, Gower Street, London, W.C., on Tuesday, October 11. Chairman, Dr. L. P. Jacks, D.Litt. Cards of admission can be obtained from the Director of Studies at University Hall, 14, Gordon Square, W.C.1.

A meeting of the Society for the Study of Inebriety will be held at Friends House, Euston Road, N.W., on Tuesday, October 11, at 4 p.m., when Professor Edward Mapother will give the seventeenth Norman Kerr Memorial Lecture on "The Physical Basis of Alcoholic Mental Disorder."

The Minister of Health (Dr. Walter Elliot) will formally open the new laboratories of the Metropolitan Water Board at New River Head, Rosebery Avenue, E.C., on Monday, October 17, at 3 p.m.

The opening address of the new session at Guy's Hospital Medical School will be given by Sir Henry Dale, M.D., F.R.S., Director of the National Institute for Medical Research, on Friday, October 14, at 3 p.m.

The forty-fourth Congress of the Italian Society of Internal Medicine will be held in Rome under the presidency of Professor Cesare Frugoni from October 19 to 22, when the following subjects will be discussed: pathology and clinical aspects of the menopause, primary myopathies with special reference to progressive muscular dystrophy, and abdominal syndromes (in combination with the Italian Society of Surgery). Further information can be obtained from the secretary, Professor Arnaldo Pozzi, R. Clinica Medica, Rome.

The first Congress of the Societies of Endocrinology of the Little Entente will be held at Bucarest from October 23 to 26. Further information can be obtained from Professor C. I. Parhon, Splaiul Independenței III, Bucarest.

At the annual conference of the National Council of Women of Great Britain in London from October 14 to 16 a number of items on the agenda will be of interest to medical women, such as the appointment of women police surgeons, the legalization of abortion, hospital pay-beds, mental health, and the community care of epileptics. Further information can be obtained on application to the secretary, 92, Gower Street, London, W.C.1.

A course in infant hygiene will be held at the Hospice des Enfants Assistés, 71, Rue Denfert-Rochereau, Paris, XIVe, from October 10 to 28 under the direction of Professor Lerchoullat and Dr. Lelong.

The Board of Control (England and Wales) (Lunacy and Mental Deficiency) changed its address on September 19, 1938, to Hohart House, Grosvenor Place, London, S.W.1. Telephone: Sloane 0828.

Sir Milsom Rees is again offering two £100 scholarships for Port Regis Preparatory School to the sons of medical men. Candidates must be under 9 years of age when the examination is held during the first week in March, 1939. Applications should be addressed to the Head Master, Port Regis, Broadstairs.

The Secretary of State for the Home Department proposes, at the expiration of forty days from September 30, to make regulations under the Factories Act, 1937, extending the provisions of Section 66 to compressed air illness. Copies of the draft regulations may be ordered through any bookseller from H.M. Stationery Office.

The editor of *Medical Life*, the only monthly journal of medical history in the English language, announces that the journal will cease publication after December.

The issue of *Bruxelles-Médical* for September 18 contains summaries of the papers read at the eleventh Congress of the International Society of Surgery, held at Brussels from September 19 to 22.

The postgraduate demonstrations arranged for the benefit of old students of the University College Hospital Medical School have been postponed for one week, until Thursday and Friday, October 13 and 14. The old students' annual dinner, to be held in the library of the Medical School, has been postponed until October 14. The annual dinner of the University College Hospital Medical Women's Association, to be held at the Langham Hotel, has been postponed until October 14. The address by Sir StClair Thomson on "Lister at University College and Hospital" has been postponed until Tuesday, October 11, at 3.15 p.m., in the lecture theatre of University College Hospital Medical School.

The tenth annual conference of the National Smoke Abatement Society at Cardiff has been postponed and will be held during November, if circumstances are then favourable.

The Health Committee of the League of Nations at a recent meeting agreed to co-operate with the Belgian Ministry of Health in making a survey of health conditions of the population and of the equipment, organization, methods and efficiency of the health services of Belgium.

On the occasion of the tenth Psychotherapeutic Congress recently held in Oxford Mr. Hugh Watts made a donation of £15,000 for the foundation of an international psychotherapeutic experimental institute.

Mr. Norman H. Davies, ambassador at large and adviser to the State Department of the United States on European affairs, has been appointed by President Roosevelt as Chairman of the American Red Cross in succession to the late Dr. Cary T. Grayson.

Dr. W. E. Thompson, the oldest doctor in the United States, celebrated his 103rd birthday at Bethel, Ohio, on July 6.

EPIDEMIOLOGICAL NOTES*

Acute Poliomyelitis

Acute poliomyelitis appears to be on the wane in Great Britain, although a dramatic fall in incidence has not occurred nor is to be expected. In England and Wales 60 cases were notified during the week under review compared with 76 in the previous week, while the numbers for London and Scotland were 3 (7) and 10 (11), respectively. More than one case was reported from the following towns: Edinburgh 6, Wembley 3, and 2 each from Braintree (rural), Edmonton, Glasgow, Hull, Manchester, Nottingham, Reading, Saltburn and Marske, and York. That the disease remains endemic in Essex and the adjoining parts of Suffolk is shown by the occurrence of 1 case each in Braintree and Bocking, Chelmsford, Dunmow, Hadleigh, Halstead, Sudbury, Melford. The 3 London cases occurred in Deptford, Islington, and Fulham.

In Germany during the week ended September 10, 419 cases were recorded compared with 365 in the previous week, chiefly in Cologne district, 97 (112), Düsseldorf 27 (24), Wiesbaden district 29 (23), Württemberg 72 (47), Bavaria 33 (31), Saxony 33 (24), 14 in Berlin and 13 in Baden. During the first thirty-six weeks of the year 2,428 cases were recorded for the whole country, compared with 1,767 during the corresponding period of 1937. In the week under review 39 cases were reported in Austria, of which 5 were in Vienna. The week ended September 17 saw a decline of the Holland epidemic, 54 compared with 58, of which 26 occurred in the Province of South Holland (Rotterdam 7, The Hague 6, and Waddinxveen district 4). During August 61 cases of paralytic poliomyelitis were notified in Denmark compared with 15 in July, while in Sweden the number rose from 56 to 268. Of the 167 cases recorded in the latter country between August 16 and 31 (59 of which were non-paralytic), 63 were in the rural regions of Jämtlands Province and 32 in the rural regions of Kristianstads Province.

Typhoid Fever

No fresh outbreaks of typhoid fever have been recorded during the week, and outbreaks already in progress have all declined to 1 or 2 cases. More than one case was reported from Coventry 3, and 2 each from Berkhamsted, Ennis-corthy (Eire), Farnworth, Glasgow, Liverpool, and London (Lambeth and Southwark). No deaths were reported from any of the principal towns specified in the table.

Primary and Influenzal Pneumonia

An increase, amounting to nearly 25 per cent. over the numbers notified in the previous week, in the incidence of pneumonia suggests that further increases may be expected in the coming weeks. The figure of 540 is greater than that for the corresponding week last year and the median value for the last nine years. London has shared in the rise, but to a less extent. Of the 23 deaths from influenza in the 126 Great Towns, there were 4 in Birmingham, 3 in London, and 2 in Liverpool.

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

Diphtheria and Scarlet Fever

The rise in the notifications of diphtheria in England and Wales has not been maintained, the figures falling from 1,213 to 1,198 (London 159 to 152). A slight fall was recorded in N. Ireland. In Scotland and Eire, on the other hand, increases continue to be reported; the chief were in Glasgow 65 (43), Edinburgh 17 (7), Lanark 12 (8), Renfrew 11 (6), and Dublin 22 (18). Of the 23 deaths in the Great Towns 4 occurred in London, 3 in South Shields, and 2 each in Barnsley, Liverpool, and Stoke-on-Trent. Two deaths were recorded in Dublin and one each in Glasgow and Edinburgh.

Increases in the incidence of scarlet fever have to be recorded for England and Wales (in which London has shared) and Scotland. Although no large outbreaks were recorded in particular areas the notifications show that the disease is on the increase generally, rural districts being involved, in comparison to their size, almost as much as towns and urban districts. Notable increases were reported from Newport 26 (18), York 18 (4), Islington 18 (9), Leicester 5 (4), Bethnal Green 13 (7), and Southwark 11 (4). While in the majority of large towns notifications were maintained or slightly increased, they fell in Manchester 23 (37), Bristol 14 (19), Glasgow 66 (69), and Edinburgh 31 (34). During the week one death was recorded in London and in Glasgow.

Measles and Whooping-cough

Two deaths from measles (in London and Leeds) were recorded in the 126 Great Towns of England and Wales compared with 3 in the previous week. In Scotland the notifications were 18 (19), the principal centres being Dundee 4 (4), Dunfermline 4 (1), Glasgow 4 (11), and Lanark 2 (0). Of the 6 deaths from whooping-cough in the 126 Great Towns 3 were in London and 1 each in Birmingham, Tynemouth, and Swansea. In Scotland there was a small rise in notifications—125 against 117: the chief increases were noted in Glasgow 109 (94), Edinburgh 4 (2), Dundee 3 (1). Two deaths were recorded (Glasgow and Paisley).

On October 1 measles and whooping-cough were made notifiable in the administrative county of London. By this order all cases occurring in a household at an interval of two months from any previous cases must be notified to the borough medical officer of health. Cases occurring in infectious diseases hospitals are exempted from the requirement.

Cholera

The incidence of cholera in Shanghai declined during the week ended September 24 from 209 to 113, while deaths fell from 70 to 46. In Eastern Kwantung cases fell during the week ended September 10 from 1,408 (380 deaths) to 936 (225 deaths). During the week ended September 24, 4,620 cases were recorded in the Central Provinces of India compared with 5,295 in the previous week. The peak of the epidemic was between August 28 and September 3.

Plague

In India plague appears to be on the increase in the week under review: in the Central Provinces 116 (68) with 6 deaths (11) and in Madras Presidency 18 (6) with 15 deaths (6); but elsewhere decreases are reported where the disease has been present—Bombay Presidency, United Provinces, and Bihar. In Burma approximately 40 cases with 35 deaths have been recorded in each of the last four weeks.

Typhus

Recently there has been a notable decrease in typhus in Egypt, Algeria, Morocco, and Tunisia, where it is usually rife. In Italian East Africa 50 cases (including 29 at Addis Ababa), 12 in the territory of Choa, and 9 at Asmara were reported in the period July 1 to September 14. In the U.S.A. 60 cases occurred from August 28 to September 3, the chief centres being Georgia 21 (22), Texas 16 (6), Alabama 13 (8), South Carolina 7 (9).

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended September 24, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns (124 in 1937) in England and Wales (including London). (h) London (administrative county). (e) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

| Disease | 1938 | | | | | 1937 (Corresponding Week) | | | | | 1929-37 (Median Value Corresponding Weeks) | |

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES ARE

EDITOR OF THE BRITISH MEDICAL JOURNAL, *Aniolog*
Westcent, London.

SECRETARY, *Medisecra* Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúir na h-Eireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Treatment of Pruritus Ani

"L. A. F." writes in reply to "J. M." (*Journal*, October 1, p. 728): I myself was for long a sufferer from pruritus ani, chiefly at night. Innumerable local applications failed to give other than partial relief. Three months ago I tried careful washing every night with soap and water, both inside and outside the anus, and so far have had "peace."

"J. P." writes to suggest a trial of "proctocaine," manufactured by Allen and Hanburys Ltd, as an improvement on their preparation "A.B.A.": the active ingredients are procaine, benzyl alcohol, and butyl-*p*-aminobenzoate. Another correspondent recommends "J. M." to try "percaine oily solution" for injection and "percainol," an ointment containing 4 per cent. percaine, both of which are prepared by Ciba Limited.

LETTERS, NOTES, ETC.

Heparin

Mr. J. E. R. McDONAGH, F.R.C.S., writes: Having undertaken some experiments with this substance I think the following remarks may be of some value to your readers. Heparin appears to belong to the class of substances which includes the cardiac glycosides and to be closely allied to bufotalin and the snake venoms. It is a reliable anti-coagulant, but it alters materially the chemico-physical characteristics of the protein. The preparation increases the sedimentation rate of the red blood corpuscles, which I consider to be due to its initial dehydrator action. It raises the refractive index of the serum and tends to increase the percentage of the blood sugar and the blood urea. Heparin usually increases the percentage of protein and invariably raises the viscosity of the plasma. Both the viscosity-refractive index and the viscosity-protein index are raised considerably. The ultra-microscopic picture is one I regard as indicating that the protein has been subjected to hydration, which I hold to be the second action of heparin. In my opinion most of the changes to be detected in the blood following the use of heparin are due to the hydration it makes the protein undergo. I look upon its anti-coagulant action as being due to this chemico-physical change, and explain the effect heparin has in correcting thrombosis in checking the dispersion, which, through a reversal of the two colloid phases characterizing this change under certain conditions, is responsible for the coagulation of the blood. Heparin acts in thrombosis similarly to "Sum 468" and in my experience has no advantage over the latter preparation, which has continued to give satisfactory results since I

first began to use it in 1923. Heparin, owing to its powerful initial dehydrator action, might prove of greater value in dispersing protein which has reached the maximum degree of hydration in such conditions as haemophilia, Addison's anaemia, and agranulocytosis, which are some of the clinical manifestations of disease produced by this chemico-physical change.

The Nature of Viruses

DR. W. M. CROFTON writes: The learned writer of your annotation of September 24 (p. 667) states that the consideration of the true nature of viruses is of purely academic interest. I beg profoundly to differ from him. My view is that the question is of first practical therapeutic importance, and for this reason that a dead antigen of a virus is a feeble one, a live virus antigen is a powerful but dangerous one, even when protected by an accompanying dose of antiserum. This is well illustrated by the occurrence of encephalitis quite commonly after the virus prophylaxis of distemper. If it can be shown that a virus is indeed microbial in nature by the demonstration that by changing its environment from a living cellular one to one free to the air—for example, from an enclosed tissue to the surface of a mucous membrane or from a Noguchi culture to the surface of a blood-agar culture—characteristic bacilli invariably grow, and that these bacilli transmit the disease and dead antigens of them prevent and rapidly cure the disease, then it seems to me proof positive that the bacillus has grown from the virus. In addition to this the bacillus is returned to a living cellular environment and, after incubation, that culture filtered through such an impeccable filter material as a Seitz disk, and the bacillus grown from the filtrate, it appears to me that this view is overwhelmingly proved. I have found a particular bacillus always associated with foot-and-mouth disease, having grown it from the blood, intact vesicles, and saliva, and with an antigen of it prevented and cured the disease in the field. By growing it in undiluted defibrinated cows' blood it rapidly goes into the virus form and is readily filtered through a Seitz disk, and the bacillary form recovered by growing it on unheated cows' blood agar. The virus of foot-and-mouth disease is so minute that its "vitality" has been called in question. Surely the demonstration that it develops into a bacillus must finally settle the question.

Psycho-physiological Aspect of Vertigo

Dr. A. MURDOCH (Bexhill-on-Sea) writes: In considering "the psycho-physiological aspect" of vertigo Dr. W. Russell Brain (*Journal*, September 17, p. 605) writes: "These two schemata [that of the external world and that of the body], however, are far from independent of each other, since the bodily schema receives contributions from proprioceptors, such as the labyrinths, which are in part stimulated by an external force of gravity, and, on the other hand, the perception of external space includes in its raw material proprioceptor impulses." It would be interesting to know from Dr. Brain how gravity can act on the labyrinth without some activating mechanism to cause displacements of the head and so alter its position in space and relative to the rest of the body. In this way only could gravity become a force and act, and, if so, what mechanism has Nature provided to ensure the delicate movements of the head which stimulate the elements in the labyrinth to function? I suggest that the atlas and axis with their specialized ligaments and muscles—the suboccipital muscles—form a mechanism specially designed by Nature for this and other essential purposes. In a previous sentence in this address Dr. Brain says "the body is represented by a constantly changing model—a plastic schema, to use Head's 1920 phrase." Is not this a function of the labyrinth, that by registering the alterations due to the functioning of the atlanto-axial-occipital muscle mechanism the whole muscular system is integrated in a co-ordinated "plastic schema"—a constantly changing model? Is it not the mechanism which explains Magnus's statement regarding his decerebrate animal—"that when the head leads the body follows"?

Disclaimer

Mr. T. POMFRET KILNER, F.R.C.S., writes: I should like to disclaim all responsibility for publicity given in a London evening newspaper on September 27 to my recent visit to the third European Congress of Plastic Surgery in Milan. I gave no information to any member of the Press, nor to anyone who would pass on information to the Press, on this subject, and it is particularly annoying to me to have such incorrect statements made about my work.

KEY TO CURRENT MEDICAL LITERATURE

*Two Cases of Pellagra treated with Nicotinic Acid. R. France, R. D. Bates, W. Halsey Barker, and E. Matthews.—p. 46.

Hyperthyroidism and Vitamin C.—The vitamin C excretion of five hyperthyroid patients on a constant diet was studied before and after subtotal thyroidectomy. In all the patients the amount excreted before operation was far less than normal. Following thyroidectomy the amount of vitamin C excreted increased in all patients, reaching a normal value in four of the five studied. Other workers claim that feeding large doses of vitamin C to animals that are receiving thyroxine improves their appearance, lessens the weight loss, and lowers the metabolic rate.

Nicotinic Acid in Pellagra.—Two cases of pellagra are reported in which nicotinic acid appeared to effect remissions as regards lesions of the skin and mucous membranes. The general strength and mental state of both patients were much improved. The low cost of this form of treatment in contrast to earlier forms of treatment is emphasized. Nicotinic acid is advocated for the treatment of patients whose food intake is by necessity very limited—for instance, in cases of persistent vomiting and anorexia, or following major surgical procedures involving the gastro-intestinal tract.

Hypoglycaemic Substance from Root of Devil's Club.—This paper presents data which show that from the root of *Fatsia horrida* an extract can be prepared exhibiting marked hypoglycaemic properties. The attention of the writers was drawn to this substance by the case of a patient who in spite of developed marked symptoms of diabetes. This patient had kept in apparent good health for several years on oral doses of an infusion of this root bark. Experiments showed that the material is active when fed by the mouth, and apparently it has no marked toxic effects.

Venesection.—The case is recorded of an 11-month-old infant suffering from a burn of the second degree involving more than one-third of the surface of the body. Recovery followed venesection, the transfusion of blood, and the injection of Ringer's solution and of a 20 per cent. grape sugar solution, most of which was introduced by the intravenous route. The rationale is discussed.

Vasectomy.—This study from a hospital in Helsingborg concerns 218 cases of hypertrophy of the prostate in which vasectomy was performed. The bilateral operation is now considered only as a prophylactic measure against the epididymitis which is apt to follow permanent catheter drainage. The incidence of epididymitis was reduced to a minimum (0.45 per cent.) in the author's material, but he had twenty cases in which other scrotal complications occurred. There were also three cases of fatal pulmonary embolism. Appreciative references are made to the Goldstein operation.

Serous Meningitis in Pfeiffer's Glandular Fever. W. Huber.—p. 692.

Serous Meningitis in Glandular Fever.—Huber has found meningeal symptoms not uncommon in glandular fever. Pathological changes in the cerebro-spinal fluid were found in two of three cases showing such symptoms; and in three of five cases in which lumbar puncture was done in the absence of meningeal symptoms a considerably increased pressure and other abnormalities were noted. In diagnosis significance attaches not so much to lymphocytosis in the blood as to the qualitative characters (here described) of the lymphatic elements.

Sources of Error.—In the period 1932-6 the Tuberculosis Department of the State Serum Institute in Copenhagen received 26,343 specimens for examination for tubercle bacilli, acid-fast and alcohol-fast saprophytes being isolated in 130 cases. More than half of them were in specimens of gastric contents. An account is given of various improvements in technique, and the risks of incorrect diagnoses being given by inadequately equipped bacteriologists are emphasized.

Heart Sounds and Murmurs in Children with Rheumatic Heart Disease. M. H. McKee.—p. 88.

Passive Vascular Exercise in Peripheral Vascular Disease.—Experiments made on the extremities of individuals immediately after death showed that a high venous pressure and hypertonic saline favoured blood flow through the vessels. When the pavaex apparatus was used under these conditions the flow was diminished in as many instances as it was increased. The clinical results of the pavaex and other forms of treatment in arteriosclerosis and thrombo-angiitis obliterans are reported. It is concluded that the value of the passive vascular exercise machine is very small. It increases venous pressure during part of its cycle, and this is believed to be an important factor in treatment; but such an effect can be achieved by very much simpler methods.

Cataract Surgery.—This is a very valuable collection of observations and hints regarding the management and conduct of cataract cases. The paper defies abstraction, and should be read at length.

Bed Reading and Examination Lamp.—The authors point out that the eye's tolerance of brightness is least in the lower half of the field, next lowest in the upper half, and highest in the plane bounding these two. A lamp for reading in bed which fulfils all the criteria necessary for good illumination is described in full. This lamp may be used for examination of the patient's eye.

Malaria Prophylaxis by Drugs.—A coloured agricultural population was divided into three intermingled groups, which were treated in various ways during the malaria season. 109 people were given 1½ grains of atebrin three weekly, and of these two developed clinical attacks of malaria; 108 were given 10 grains of quinine daily, and of these six developed attacks; whereas of 120 untreated controls thirty-seven manifested clinical attacks. No toxic reactions to atebrin were observed.

Reticuloocyte Infection with *P. vivax*.—*P. vivax* showed a definite tendency to invade reticuloocytes rather than mature erythrocytes.

Erythrocyte Susceptibility to *P. vivax*.—The relative percentages of young and mature blood cells which show infection in the peripheral blood may be dependent solely on the relative proportions of young and mature cells at the site of sporulation; therefore invasion of the reticuloocytes by *P. vivax* may not be due to any preferential selection on the part of the parasites, but merely to circumstances.

Distribution of Boron in Organs of White Lily. G. Bertrand and L. Silberstein.—p. 104.

Nomenclature of Sporing Anaerobes.—This is a protest against the heterogeneity of the genus *Clostridium* as at present constituted, and against the adoption of criteria such as pathogenicity and physiological properties in classification, to the disregard of morphology. Prévot proposes that 132 species of so-called *Clostridium* should be reclassified in two genera (each subdivided into two families according to their Gram-staining reactions): *Clostridium*, having a central or subterminal spore; and *Plectridium*, having a terminal spore. This is a return to nomenclature proposed by A. Fischer forty-one years ago.

Antirabic Vaccination.—Against experimental rabies in guinea-pigs a virus suspension treated with formalin was found to be a better immunizing agent than suspensions treated either with phenol or phenol combined with ether. Two doses immunize better than one, but the difference is not so great as to contraindicate the single dose when circumstances demand it.

Importance of Autonomic Nervous System in Internal Secretory Function of Anterior Lobe of Pituitary. L. Herold and G. Effkemann.—p. 389.

Comparative Study of Ovarian Function.—To avoid the somewhat dangerous method previously in use for registering the contractions of the uterus in animals the author suggests that those of the vagina, being parallel to the uterine movements, can be taken as a substitute. For this purpose he has devised a balloon method for registering vaginal contractions. This has the advantage of allowing the rapid biological assay of ecbole and other drugs, and has provided an easy and valuable experimental method.

Recent Advances in Knowledge of Anterior Lobe of Hypophysis. E. H. Rymanson and C. H. Hodgson.—p. 160.

Acute and Chronic Mediastinitis.—On the basis of an experience of sixty cases of mediastinitis the clinical pictures produced by this disease in its different forms are outlined. Infection occurs more commonly in the posterior mediastinum, and is often the result of perforation of the oesophagus or suppurating lymph glands. Anterior mediastinitis follows most often infection in the neck or osteomyelitis of the sternum. In the majority of cases the prognosis is grave because of the nature of the lesion to which the mediastinitis is secondary, but when the condition is localized surgical treatment offers good results.

Archives of Ophthalmology

Chicago vol. 20 July, 1938

*Testing Fitness for Night Flying. Visual Acuity. C. E. Ferree and G. Rand.—p. 58.
Biochemistry of Lens: XI, Effect of Galactose on Permeability of Capsule of Lens. J. Bellows and L. Rosser.—p. 80.

Streptococcal Conjunctivitis.—An epidemic of acute conjunctivitis at a boys' summer camp was found to be due to *Strep. viridans*. This is usually considered to be a rare causal organism. The discharge was at its height in twelve hours and declined at the end of forty-eight hours. Cure was effected in seven and a half days on an average. Various forms of treatment failed to alter the natural course of the infection.

Fitness for Night Flying.—The ability to see at night and in low degrees of illumination should be tested. The effect of dark adaptation on this ability should be determined, as also the amount and speed of dark adaptation. A suitable instrument for carrying out these tests is described.

Dehydrophosphorylation in Muscle Extracts. R. K. Pillai.—p. 1087.

Vitamin K.—The curative blood-clotting method has been subjected to a thorough revision, a tissue extract of constant activity being made by putting up an extract of hen's muscle in ampoules and storing it in a frozen condition. The activity of the tissue extract was measured against the plasma of a series of normal chicks. A certain dried spinach powder formed into tablets and stored under precautions securing stability was selected as a standard of vitamin K, used for the construction of a curve of reference, and was found to contain 500 units per gramme. Dam and Glavind discuss the limits of error, and add that it was not possible to render the coagulability of the blood plasma "supernormal" by administering large doses of the standard substance.

Synthetic Immunochemistry.—Clutton, Harington, and Yuill describe the preparation and properties of thioxyal derivatives of horse serum globulin and albumin and of thyroglobulin. They have studied the serological reactions of the derivatives and found them to be conditioned by the thyroxine groups introduced which thus act as haptens, the hapten property being a function of the whole aromatic portion of the thyroxine molecule and not of the diiodophenolic group alone. Passive immunization with antisera against the thioxyalproteins protects against the normal physiological effects of exogenously administered thyroglobulin and thyroxine. The general implications of this observation are discussed.

Indophenol-reducing Capacity of Guinea-pig Leucocytes. A. E. Kellie and S. S. Zilva.—p. 267.

Antitoxin Purification.—Fibrinolysin and other enzymes separate the antitoxic pseudoglobulin molecule into components with different physical and chemical properties. One of these is non-antitoxic and has a low denaturation temperature; the other is antitoxic and is less easily denatured. The latter, purified by these methods, is not only more free from inert proteins than preparations of antitoxin hitherto obtainable, but owing to smaller molecular size has new therapeutic properties.

Crystalline Virus.—The extraction of plants infected with tomato bushy stunt virus yields a crystalline protein which is believed to be the virus itself. It forms true crystals (mainly rhombic dodecahedra), whereas previous preparations of this kind, such as those of tobacco mosaic virus, have consisted of fluid crystals. Antiserum, which is easily prepared, causes a fine granular and compact agglutination; this is likened to "O" agglutination among bacteria, and that of crystalline tobacco mosaic virus to "H," the difference being presumably related to the shape of the crystal. Chemical and physical methods of disinfection cause loss of infectivity without loss of crystalline form or serological specificity.

Investigation into Dosage Delivered by Certain Techniques in Radiation Therapy of Carcinoma Cervix. B. Sandier.—p. 623.

Some Direct Measurements of the Gamma-ray Dose.—The results of direct measurements of the dosage delivered to malignant lesions of the tongue by interstitial radium therapy show that the minimum dose which will give a satisfactory clinical result is of the order of 5,000 r. In many cases, however, the minimum dose reaches values of the order of 10,000 r, while those parts of the lesion near to needles may receive very much more than this. The results also suggest that the threshold dosage rate for squamous-celled carcinoma must be below 0.473 r per minute.

*Acute Arterial Lesions in Rabbits with Experimental Renal Hypertension. C. Wilson and G. W. Pickering.—p. 343.

Blood-pressure-raising Reflex from Muscle.—Exercise of a limb raises the blood pressure and pulse rate. If the exercise takes place when the circulation is occluded these remain raised until the circulation is restored. This reflex from the leg was absent in a patient whose leg was completely anaesthetic.

Raynaud's Disease and Preganglionic Sympathectomy.—Attacks of Raynaud's disease can be induced by cooling the fingers after preganglionic sympathectomy. It is concluded, therefore, that the attacks are due to a local vascular fault and not to excessive action of the vasomotor system.

Arterial Lesions in Experimental Hypertension.—In rabbits hypertension produced by constriction of the renal artery causes arterial lesions indistinguishable from those found in malignant hypertension in men. The incidence of the lesions is related to the degree of hypertension. These results support the view that hypertension causes the associated arterial changes, and not that the arterial changes cause the hypertension.

- Intra-uterine Amputations and Annular Constrictions in Living Infant due to Amniotic Adhesions Resulting from Oligohydramnios. Y. N. Ajinlyu.—p. 692.

Prophylaxis of Constriction Ring Dystocia.—The author, whose experience is very extensive, believes that contraction ring is an extension of local colic in an irritable uterus, and that it can be prevented by early recognition of this type of hyperaction in the early stages of labour. The pain that extends beyond the cessation of the actual uterine contraction denotes that colicky action has started and must be controlled at once by morphine or heroin, a procedure which will often avoid the complications of a troublesome contraction ring.

- *Erythema Annulare Rheumaticum. H. Abramsen and A. M. Tunick.—p. 94.

Drugs Transmitted through Breast Milk.—Experiments have shown that both the barbiturates and the bromides are transmitted to the infant by the mother in her milk. These drugs were given to mothers in a maternity hospital and the milk was then analysed. The infants also showed the effect of the drugs by becoming less irritable, but they may be adversely affected if large doses are used.

Erythema Annulare Rheumaticum.—This condition is of significant value in the diagnosis of rheumatism, and is occasionally met with in chorea. It may be found between attacks of rheumatism, but is of no prognostic value and does not reflect the degree of their severity.

- Effect of Adrenaline on Blood Pressure in Schizophrenia. A. Mazza.—p. 479.
- Duke's Test in Mental Disease. G. Zonta.—p. 523.

Cerebral Muscular Atrophy.—Ottonello reviews theories of causation of early muscular atrophy in the course of hemiplegia and describes four cases with microscopical investiga-

tions. He concludes that the primary peripheral neuronic degeneration which is responsible may not be due entirely to interruption of cerebral stimuli; it results from a toxic process affecting electively the paralysed side on account of locally lowered resistance.

Cataleptoidism and Motor Hypersuggestibility.—Little evidence of motor hypersuggestibility was found in ten "unstable" children aged 10 to 11 presenting cataleptoid manifestations and perseveration.

Zeitschrift für Infektionskrankheiten, Parasitäre Krankheiten und Hygiene der Haustiere

Berlin vol. 53 August 12, 1938

- *Recent Results in Physico-chemical Investigation of Filterable Viruses W. Frei.—p. 253.
- *Virus Studies in Rabies. F. Gerlach.—p. 279.
- Stephano-filaris in Dutch East Indies and Similar Infections in Other Countries. F. C. Kraneveld.—p. 291.
- *Chief South African Poison Plants. D. G. Steyn.—p. 332.

Nature of Filterable Viruses.—Recent research on ultra-visible particles is reviewed, and the theory is advanced that as between living and non-living substance there is no fundamental difference but a step-like gradation, and the same applies to the cellular and the non-cellular. Viruses stand on the boundary line.

Virus Studies in Rabies.—An illustrated description of groups of granular bodies, intracellular and extracellular, found in the nerve tissues and in certain fluids of infected animals. Methods of demonstration, isolation, and culture are given.

Poison Plants of South Africa.—This is a list and illustrated description of the native plants giving rise to poisoning of domestic animals (chiefly sheep) in pasture land.

Zeitschrift für Tuberkulose

Leipzig vol. 80 July, 1938

- *Bilateral Extrapleural Pneumothorax. G. Sauer.—p. 217.
- Respiratory Insufficiency in Cavernous Pulmonary Tuberculosis. H. Rothblat.—p. 228.
- Skin Tuberculosis in Relation to Tuberculosis in General: Findings in Examination of 525 Patients suffering from Skin Tuberculosis and Investigation of their Environment. H. P. Bott.—p. 237.
- Medicinal Therapy in Pulmonary Tuberculosis (Experiences with Estrol and Siran). H. Grebe.—p. 245.

Bilateral Extrapleural Pneumothorax.—A well-illustrated account of twelve cases. Fourteen of the pneumolyses were maintained with air, eight required oil later (in one patient on both sides), and two, because of complications, were followed by a thoracoplasty. A clear indication for bilateral pneumothorax is present in the patient with bilateral small or medium-sized apical cavities in whom the collapse obtained by an intrapleural artificial pneumothorax, even if practicable, would encroach too much on the patient's respiratory reserve.

Zeitschrift für Urologie

Leipzig vol. 32 1938 Heft 8

- Investigations of Liver Function in Uraemia. A. Babics and A. Torka.—p. 533.
- Discussion of Cases with Reference to Differential Diagnosis of Kidney Tumours by Pyelogram. H. B. Sprung.—p. 539.
- Generalized Calcifications of Lymphatic Glands in Course of Left-sided Renal Tuberculosis. F. Laufer.—p. 543.
- Bladder Calculus accompanied by Bladder Carcinoma in Case of Clinically Proved Hyperparathyroidism. T. Kusonoki.—p. 545.

"Uraemia" in Prostatic Hypertrophy.—The chemical pathology of the uraemic syndrome in patients suffering from prostatic hypertrophy is briefly discussed, and the authors have reached the conclusion that acidosis plays a very large part in the production of this syndrome. Accordingly they advise that the alkali reserve of the plasma be determined in these cases and, if necessary, the deficit should be made up by giving a 1 to 3 per cent. bicarbonate solution intravenously. To prevent alkalosis supervening they stress the necessity for calculating the amount of bicarbonate needed in the individual patient.

IMMUNITY *against* WINTER'S COLDS

Dissolved Vaccines G.L. bring to Cold prophylaxis the assurance of success in the majority of cases. For although the primary infecting agent in the common cold is still a subject for research, enough is known about the secondary invaders to produce an effective vaccine for prophylaxis and treatment.

Inoculation with Cold Dissolved Vaccine G.L. releases, for immediate utilisation, the antigens of the organisms responsible for the acute secondary stage of the cold. Retention of full antigenic power excites

a rapid and potent response from the body's defence mechanism. Moreover—because the antigens are detoxicated—a maximum dose (1-1 cc.) may be given from the first without fear of undesirable reactions.

Immunity is developed rapidly; three injections at intervals of a week (starting in the early autumn) usually sufficing for the whole winter. Finally—with the Dissolved Vaccine G.L. anti-body production is sufficiently speedy to shorten an actual attack. If injections start when the first symptoms appear.

COLD DISSOLVED VACCINE G.L.

In rubber-capped bottles:
5 cc., 7/6; 10 cc., 10/9;
25 cc., 17/6. Less usual
professional discount.

The Product of Unique Experience ADRENALIN (P., D. & CO.)

Full particulars of Adrenalin (P., D. & Co.) and its uses will be supplied on request.

PARKE, DAVIS & CO. introduced Adrenalin to the medical profession in 1901. During the thirty-seven years that have elapsed, they have manufactured it continuously, and their long experience enables them to offer a *natural* product that is unsurpassed in effectiveness and purity.

ADRENALIN (P., D. & Co.)—the original and well-tried preparation—is extracted from the medullary portion of selected adrenal glands. The isolated substance is then standardized by both physiological and chemical methods to secure full activity of the finished preparation.

Medical men can make sure of obtaining Adrenalin products that are potent, uniform in action, and reliable, by specifying "P., D. & Co."

Panties

BY J. ROUSSEL

IMPROVE HEALTH & FIGURE

Designed in consultation with the medical profession, Panties by J. Roussel afford necessary support to the lower abdomen without undue constriction. The varied tension of the elastic weave—exclusive to creations by J. Roussel—exerts a gentle massaging action which disperses superfluous tissue and stimulates circulation through the abdominal region. While the figure thus regains the natural line of youth, the system is toned up and the organs encouraged in their natural functioning. Doctors may permit patients to wear Roussel Panties in complete confidence that both health and figure will benefit. * Full particulars of other figure-control creations by J. Roussel which are equally beneficial to general health are given in our illustrated catalogue. We shall be pleased to send you a copy. Please ask for booklet K. * A reduction of 2/- in the £ is made on purchases for personal use by members of the Medical Profession.

For the EARLY PREVENTION OF VITAMIN & MINERAL DEFICIENCY IN INFANTS

It is now a widely recognized fact that infants need vegetable food as early as possible in order to balance and augment the usual milk diet. The difficulty, hitherto inseparable from vegetable in any form, has been the intestinal disturbance—notably diarrhoea—of which inability to digest the tough fibrous tissue surrounding the food cells is the primary cause.

By the Libby process of Homogenization this fibrous covering is broken up into fine particles which provide non-irritant bulk and smooth, easy elimination. The nutriment is of course at the same time released so that it comes into direct contact with the digestive enzymes.

There are six scientifically formulated combinations of Cereals, Vegetables and Fruit in Libby's Homogenized Foods which can be prescribed in any case where Vitamin and mineral deficiency is indicated, and have been given successfully to infants as young as 12 to 8 weeks.

A partial analysis of one combination, set out in the table below, shows how the deficiencies in any one vegetable are compensated for by the values in the others.

PARTIAL ANALYSIS OF A GROUP OF VEGETABLES

| | Spinach | Carrots | Peas |
|------------------|---------|---------|------|
| Protein | 2.1 | 1.1 | 3.6 |
| Fat Per Cent. | 0.3 | 0.4 | 0.2 |
| Carbohydrates | 3.2 | 9.3 | 9.8 |
| Calcium | 67 | 56 | 28 |
| Phosphorus | | | 127 |
| Mg. per 100 gms. | 68 | 46 | |
| Iron | 2.5 | 0.6 | 2.0 |
| Vitamin A | +++ | +++ | ++ |
| Vitamin B | ++ | ++ | +++ |
| Vitamin C | +++ | ++ | ++ |
| Vitamin G | ++ | ++ | + |

Samples together with clinical data and laboratory reports will be gladly supplied upon request to Messrs. Libby, McNeill & Libby Ltd., 15, Lime Street, London, E.C.3.

Duo-Therapy

Sunshine for your patients

There is no reason why you should go without the benefits which actinotherapy brings to both practitioner and patient. But your results depend largely on effective apparatus. No skill or study will enable you to overcome self-imposed defects due to inadequate or outworn equipment.

Specify the Hanovia Duo-Therapy Unit and have a lamp which is always dependable, always ready for use, always constant in its high intensity of ultra-violet radiation. Remember that this Unit combines the most modern ultra-violet ray lamp (the self-starting electronic Alpine Sun) with the standard therapeutic infra-red lamp (the new Sollux Lamp, Model V.). So the Duo-Therapy Unit enables you to apply any group and combination of rays needed for modern actinotherapy, in full therapeutic intensity, following the best technique, and using a dependable, responsive instrument.

This is why most practitioners now specify the Duo-Therapy Unit for their consulting rooms, and why so many users of older ultra-violet lamps avail themselves of our part-exchange terms for replacement with this up-to-date Unit.

The coupon is for your
convenience

HANOVIA, Ltd.,
SLOUGH.

To Hanovia Ltd., Slough.

Dear Sirs,

Please send full particulars of the Duo-Therapy unit (mention if part-exchange required).

The new Victor F-3 X-ray Unit

The wide range of usefulness of the new Victor F-3 X-ray unit is illustrated throughout the complete set of F-3 technique charts. Shorter exposures, in addition to this versatility, are made possible by a 220% increase in radiographic power. And there is no increase to the original low price even though the facility of rapid interchangeability between portable and mobile service has also been added. All these and many other advantages recommend the Victor F-3 to the study of the busy radiologist whose main X-ray plant cannot always conveniently serve the demands his practice makes upon it.

STUDY THESE FEATURES

Portable and mobile * Wide range * Shockproof * Climate-Proof * Easy to use * Operable from any plug point * Highly flexible and adaptable * Compact case only 21 x 14 x 8 inches * Weighs only 15 lbs. * Complete technique charts * Long-life, genuine Victor Coolidge tube * Accurate timer * Foot switch for screening * Convenient terms if desired *

For a demonstration without obligation, or the free descriptive booklet, simply fill up and post the convenient coupon.

SALT AIR SURGICAL SERVICE

Undeniably
EFFICIENT

Certainly
COMFORTABLE

● The efficiency of Salt's Patent Kidney Belt has been proved in more than 30,000 cases . . . indeed, it has come to be regarded as the standard sup-

port of its kind. Made for the individual wearer in every-instance, the belt is always completely comfortable. It gives firm support *under* the kidney, retains the kidney in its proper position and obviates symptoms due to dragging on the renal ligaments. Practitioners are invited to apply for copies of Salt's Corset & Belt Book, which gives full details and Measure/Order forms for all the Saltair appliances, including

An AMPLIVOX TO WEAR

With CRYSTAL MICROPHONE
STANDARD BATTERIES
WEIGHING ONLY 1½ LBS.
AVAILABLE IN 3 DIFFERENT TONES

The introduction of the Model W AMPLIVOX has a special significance in view of the recent official medical recommendations for valve amplifier hearing aids. It effectively solves the problem of providing a high quality hearing aid with low upkeep costs, offering extreme simplicity and reliability to those who want the smallest possible instrument. It will go into a gentleman's hip pocket or lady's handbag with ease. It can readily be adapted to the Amplivox inductor system for Telephone or theatre listening and so provides the most complete hearing aid ever made. I shall be glad to send you descriptive literature if this is not already in your possession.

representatives in all principal countries overseas.

Question

What gives the most effective abdominal support?

Answer DIRECT anterior-posterior pressure.

Question Why is this?

Answer It gives even, positive pressure where the body most needs it.

Question Where is this form of support found at its best?

Answer In the Curtis Abdominal Support No. 1.

Question What are its outstanding features?

Answer No undue constriction of the lower abdomen. Extremely light. Maximum support is combined with complete freedom of the hips. Medically approved in the treatment of all forms of abdominal ptosis—visceroptosis, enteroptosis and gastropptosis—and for the support of scar tissue during consolidation.

As good as a second right hand in the surgery

Yet another tremendous advance in surgery examination lamps—the Ceiling Model Terry Anglepoise. Out of the way, yet instantly to hand at a touch, pouring its strong, penetrating, concentrated beam right on to the spot, without any distracting glare in the user's eyes. Will practically reach to any part of the average surgery, thus avoiding awkward light-shifting when the patient must not be moved. Leaves both hands free. A perfect examining and dressing lamp. For sheer efficiency and convenience nothing can simply approach the ANGLEPOISE—adjustable to 1,001 positions at a finger touch—and poised at any angle. Simply marvellous for all "close" work as it throws the clear light necessary for extreme accuracy. It can be brought as close as required. Saves on light bills—a 25 watt bulb works like a 60! Scientifically built—every part superlatively made. Chromium plated arms, tireless springs—for perfect balance. In several models. Models for fixing to wall or table, and on smooth-running castors. "A Triumph for Terry Springs." Prices from 50/- (U.K. only). Patented at Home and Abroad.

NOTE THE ANGLES

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Bland. The iron content remains fresh and unoxidized indefinitely, and

injury to teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.
The Iron Jelloid Company, Ltd., King George's Avenue, Watford, Herts.

Toxæmias of Faulty Metabolism

SALVITAE enables the physician to control elimination and alkalization, thus dealing fundamentally and effectively with the Toxæmias of Faulty Metabolism.

SALVITAE

SALVITAE increases the alkalinity of the blood and tissues, prevents the over-production of nitrogenized materials, improves oxidation and stimulates the natural activity of the eliminative organs.

Professional samples and literature gladly sent on request.

CRICHTON ROYAL, DUMFRIES

FOR
NERVOUS AND MENTAL DISORDERS.

This Hospital has every facility for complete investigation of the above conditions, and provides all forms of modern treatment including psychotherapy, physiotherapy, and recreational therapy. Cases of alcoholism and drug addiction are admitted. The fully equipped for X-ray work, heliotherapy, short-wave (swimming bath, prolonged baths, Scotch and Vichy douches, Plombières treatment, electric and Turkish bath cabinets, etc.). There is a fully equipped gymnasium under qualified instructors. Facilities are provided under special recreational therapists for all indoor and outdoor games, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens. The Hospital has its own Cinema, Library and Hairdressing Saloon. Terms include regular motor drives. Private rooms, suites, or villas are available and special nurses can be provided.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country and include an extensive farm (F.T. herd), gardens and orchards.

As the Hospital is well endowed terms are exceptionally moderate, e.g. First Department, 3 to 30 guineas per week; Second Department, 2 and 24 guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For details, necessary forms, and further information apply to:

Physician Superintendent, P. K. McCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law.
Tel.: Dumfries 1119.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBIDGE, SUFFOLK**

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: **WICKHAM MARKET 216** (Toll Call from London.)

Proprietors: The Norwood Sanatorium, Limited.

BOWDEN HOUSE,

HARROW-ON-THE-HILL,

For the residential treatment of Functional Nervous Disorders

No case under certificate nor under the M.T.A.

This home, which was founded in 1911, is designed to provide for psychoneurotics a curative environment associated with modern psychological treatment modified to suit each individual patient. The treatment is in the hands of three experienced psychotherapists, and most patients receive three hours of analytical treatment per week. Occupational therapy of many varieties is available but not obligatory. Recreations include tennis, badminton, billiards, etc.

On admission patients are examined by the diagnostic physician, who advises on all physical treatment. As far as possible all necessary pathological examinations are carried out by the pathologist in the laboratory on the premises.

STAFF:

H. CRICHTON-MILLER, M.A., M.D., M.R.C.P. (Senior Physician). GRACE H. NICOLLE, M.A., M.B. (Resident Physician).
ALFRED TORRIE, M.A., M.B., Ch.B., D.P.M. (Medical Superintendent). MARY HALL, M.B., B.Ch. (Pathologist)

RUTHIN CASTLE, NORTH WALES

A Private Hospital or Clinic for the diagnosis and treatment of Internal Diseases (except Mental or Infectious Diseases). The Clinic is provided with a full staff of doctors, bacteriologists, chemists, radiologists, dietitians, nurses, masseurs, and masseuses.

The surroundings are beautiful. The climate is mild. There is central heating throughout. The annual rainfall is 30.5 inches, that is, less than the average for England.

The inclusive weekly fees are from 15 guineas a week, according to the room occupied; rooms with bathroom are from 21 guineas. The charges include all chemical, bacteriological, X-ray or other examination advised by the doctors, and all the usual forms of treatment, in addition to board and lodging. There are no extra charges except for alcohol (when ordered) and laundry. An examination and consultation fee of 15 guineas is charged on the first visit.

Address: THE SECRETARY, Ruthin Castle, North Wales.

Telegrams: Castle. Ruthin. Telephone: Ruthin 66

HOLLOWAY SANATORIUM VIRGINIA WATER

A Registered Hospital for the Treatment of MENTAL DISORDERS of the EDUCATED CLASSES. Founded by THOMAS HOLLOWAY in 1885.

This Institution is situated in a beautiful and healthy locality within easy reach of London. It is fitted with every comfort. Patients can have Private Bedrooms and Special Nurses, as well as the use of General Sitting Rooms, at moderate rates of payment. Voluntary Patients can be admitted.

There is a Branch Establishment at CANFORD CLIFFS, BOURNEMOUTH, where Patients can be sent for a change and be provided with all the comforts of a well-appointed home.

For Terms, apply to

The Resident Medical Superintendent, St. Ann's Heath, Virginia Water, Surrey.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

INCORPORATING THE ROSS INSTITUTE.

POSTS OVERSEAS FOR MEDICAL MEN

A register is kept in the School of medical men who are prepared to be considered for posts overseas, and the School is frequently asked to advise plantation and mining companies when such posts fall vacant.

The salaries offered are attractive; conditions of service are governed by standardised forms of contract; and many of the posts offer to medical men a most interesting field in which to practise their profession.

It is desirable that candidates for posts overseas should hold a diploma in tropical medicine and hygiene. The course provided by the London School for the Conjoint Board's Diploma lasts six months and the tuition fee is £40. The course may be taken from October to March or from January to June. There are generally more vacancies in the course commencing in January.

The Director of the Ross Institute is always glad to interview medical men who would like information regarding the possibilities of a career overseas if they will be good enough to make an appointment to call on him. Enquiries may be addressed to

The Director,
Ross Institute of Tropical Hygiene,
London School of Hygiene & Tropical Medicine,
KEMPEL STREET, GOWER STREET, W.C.1.

LONDON HOSPITAL MEDICAL COLLEGE

(University of London).

SCHORSTEIN MEMORIAL LECTURE.

BRITISH POSTGRADUATE MEDICAL SCHOOL

UNIVERSITY OF LONDON.

ASSISTANTSHIP IN MORBID ANATOMY.

Applications are invited for the post of Assistant in Morbid Anatomy in the Department of Pathology.

The stipend offered is £300 per annum, rising by annual increments of £50 to £500. The successful candidate will be required to join the Federated Superannuation System for Universities.

Further information can be obtained from the Professor of Pathology.
Applications, with copies of not more than three testimonials, should be submitted to the Dean, British Postgraduate Medical School, Duane Road, London, W.12, to arrive not later than the first post on Monday, October 17th, 1938.

CITY OF LEEDS

ASSISTANT CLINICAL TUBERCULOSIS OFFICER

Applications are invited for the post of Assistant Clinical Tuberculosis Officer. Applicants should be duly qualified and registered medical practitioners, and must have had not less than three years' postgraduate experience, including experience in general medicine, surgery, and radiology, and in the treatment of tuberculosis at a dispensary or in a hospital, sanatorium or other institution reserved for such cases. Preference will be given to candidates with experience in the treatment of non-pulmonary tuberculosis. The possession of a D.P.H. though not essential, would be considered an additional qualification. The present grading scheme of the Corporation provides for a commensurate salary of £500-£600 per annum according to qualifications and experience, with annual increments of £25, subject to satisfactory service, to the maximum of £700 per annum. The first increment will take effect on April 1st following the completion of twelve months' service. The person appointed will be required to pass a medical examination and contribute to the Superannuation Fund, established under the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on a form to be obtained from the undersigned, together with copies of three recent testimonials, and endorsed "Tuberculosis Officer," must be received at the Health Department, 12, Market Buildings, Vicar Lane, Leeds, 1, not later than 10 a.m. on Saturday, October 15th, 1938. Canvassing in any form, either directly or indirectly, will be a disqualification.

J. JOHNSTONE JERVIS,
Medical Officer of Health.

MIDDLESBROUGH EDUCATION COMMITTEE

APPOINTMENT OF SENIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified men for the post of Senior Assistant School Medical Officer in connection with the Medical Inspection and Treatment of School Children and such other duties as may be required by the Education Committee. The person appointed will be responsible to the School Medical Officer.

Commencing salary £500 per annum (provided the candidate has had not less than three years' postgraduate experience) rising by annual increments of £25 to £700 per annum. Previous experience as an Assistant School Medical Officer shall be reckoned in calculating the appropriate commencing salary. The successful candidate will be required to devote his whole time to the duties of the office. The appointment will be subject to two calendar months' notice on either side, such notice to date from the last day of any calendar month.

Applicants should have had experience in the work of School Medical Inspection, and preference will be given to candidates who have had experience of Refraction work and in the work of School Clinics and who are recognized by the Board of Education in connection with certification under the Mental Deficiency and Other Acts.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the successful candidate passing a medical examination to the satisfaction of the Medical Officer of Health.

Forms of application may be obtained from the Director of Education on receipt of a stamped addressed foolscap envelope, and these should be returned to the Director of Education, Education Offices, Middlesbrough, not later than Saturday, October 15th, 1938.

Canvassing in any form will disqualify.
PRESTON KITCHEN, Town Clerk

Town Clerk's Office, Middlesbrough, September 26th, 1938.

GENERAL POST OFFICE

HEADQUARTERS MEDICAL BRANCH (FEMALE STAFF.)

There will shortly be a vacancy for an ASSISTANT WOMAN MEDICAL OFFICER in the Headquarters Medical Branch. The appointment will be pensionable, and will carry a salary commencing at £500 a year and rising by annual increments of £25 to £700 a year. The rates of salary are liable to review.

Each candidate must be a fully qualified medical practitioner, a natural-born British subject, and the child of a person who is, or was at the time of death, a British subject. Candidates must also be unmarried, or widows. Preference will be given to candidates under 30 who have held one or more Hospital appointments. The successful candidate will not be allowed to engage in private practice in addition to her official duties.

Applications, stating qualifications, age, etc., with copies of any recent testimonials, should be sent to the Chief Medical Officer, General Post Office, London, E.C.1, not later than October 31st, 1938. Political influence should not be sought in support of applications; it would prejudice rather than assist the candidature.

The Female Medical Staff at Headquarters consists of a senior Woman Medical Officer and five Assistant Women Medical Officers. Information as to the duties can be obtained from the Chief Medical Officer.

Candidates may be required to attend for personal interview in London at their own expense.

LONDON COUNTY COUNCIL

Applications invited from Medical Practitioners of at least one year's standing for under-qualified positions. Candidates must have held resident appointments in a general hospital for at least six months. Married quarters not available.

ASSISTANT MEDICAL OFFICERS (Grade II)—Salary £250 a year, together with board, lodging and washing. Appointment for one year only in first instance (renewable for a second year under certain conditions).

(a) **OWLWICH HOSPITAL**, East Dulwich Grove, S.E.22 (two positions):

(1) Outlets mainly medical, obstetrical experience desirable.

(2) Outlets mainly medical, experience in anaesthetics desirable.

(b) **QUEEN MARY'S HOSPITAL**, Sidcup, Kent—Outlets mainly medical (male convalescent hospital), surgical experience desirable.

(c) **ST. JAMES' HOSPITAL**, Orsey Road, Barking, S.W.12—Outlets: obstetrical, gynaecological and anaesthetic experience essential.

(d) **ST. MARY ISLINGTON HOSPITAL**, Highgate Hill, N.19—Duties mainly medical.

(e) **ST. MATTHEW'S HOSPITAL**, Shepherdess Walk, N.1—Medical duties.

Applications forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division, 2a, County Hall, S.E.1, returnable by October 17th.

Canvassing disqualifies.

MIDDLESEX COUNTY COUNCIL

MIDDLESEX COUNTY COUNCIL MATERNITY HOSPITAL, Heathborne Road, Rushley Heath, Herts

RESIDENT ASSISTANT MEDICAL OFFICER (woman) required to be registered medical practitioner, preferably M.C.O.G. or D.C.O.G., with previous resident appointment in general hospital and special experience and knowledge of obstetrics.

Appointment for four years only subject to medical examination, it held during pleasure of Council, and terminable by one month's notice on either side.

Salary £400-£475 p.a., with board, lodging and laundry valued at £100 p.a. Contributions to Superannuation Fund will be required from April 1st, 1939. Possibility of retention on established staff, with £500 p.a. max.

Whole-time duties, such as County Council may direct, under supervision of Medical Superintendent and Obstetric Surgeon of Redhill County Hospital, under which the Maternity Hospital is administered as an annexe. Duties include medical charge of the 48 beds and attendance at ante-natal clinics at Redhill.

Written applications, with copies of not more than three recent testimonials, to be sent in under sealed (in envelope endorsed "Mat Hosp—A.M.O.") by October 15th, 1938—disclosing relationship to any member or officer of Council. Canvassing, direct or indirect, disqualifies.

Gulldhal, C. W. RADCLIFFE, Town Clerk of the County Council S.W.1.

CITY OF LEICESTER

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (FEMALE)

The Council invite applications for the appointment of an Assistant Medical Officer of Health and Assistant School Medical Officer.

Applicants must be under 40 years of age and possess the Diploma in Public Health, or a similar qualification.

Salary £500 per annum, rising by annual increments of £25 to £700 per annum.

The post is a designated one under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination. The duties will be primarily in connection with the School Medical and Maternity and Child Welfare Services, but may include any other duties properly assigned from time to time.

Application forms may be obtained from Dr. E. K. Macdonald, Medical Officer of Health, Health Department, City Friars, Leicester, and should be returned in him, with copies of not more than three testimonials, not later than October 15th, 1938.

Town Hall, Leicester. L. McVOY, Town Clerk
September 21st, 1938

CITY OF COVENTRY

TEMPORARY ASSISTANT MEDICAL OFFICER OF HEALTH FOR AIR RAID PRECAUTIONS

Applications are invited from registered medical practitioners—preferably from medical officers retired from the Services—for the above post, which will be for one year in the first instance. The salary will be £500 per annum, but will be suitably reviewed if the appointment is continued beyond the first year. The duties of the appointment will be full-time and under the direction of the medical officer of health, they will consist mainly in training volunteer personnel in first-aid and in assisting with the administration of the casualty services section of the City A.R.P. Scheme.

Applications, stating age, qualifications, and experience, should reach the undersigned by October 12th, 1938.

The Council House, A. MASSEY, M.D., Coventry. Medical Officer of Health
October 1st, 1938.

BOROUGH OF WORTHING

DEPUTY MEDICAL OFFICER OF HEALTH

Applications are invited for the above appointment from duly registered medical practitioners, possessing a diploma in Sanitary Science, Public Health or State Medicine. Salary £650 per annum, rising by annual increments of £25 to a maximum of £700 per annum, and a motor-car allowance of £50 per annum. Terms and conditions of appointment and forms of application will be supplied on receipt of a stamped and addressed foolscap envelope.

Applications, with not more than three recent testimonials, must be received by the undersigned not later than October 14th, 1938.

Town Hall, WORTHING. J. KENNEDY ALLERTON, Town Clerk.
October 1st, 1938.

HULL CORPORATION HEALTH DEPARTMENT.

ASSISTANT MEDICAL OFFICER OF HEALTH (Female).

Applications are invited from duly qualified unmarried or widowed medical women, under the age of 40 years, and of not less than three years' standing in their profession, for the post of Assistant Medical Officer of Health.

Salary £200 per annum, rising, subject to satisfactory service, by annual increments of £25 to £250.

The duties consist mainly of work in the Maternity and Child Welfare Department, the School Medical Service, and the Tuberculosis Department.

Candidates must have had special experience in Paediatrics, and preference will be given to those possessing the Diploma in Public Health, or an equivalent qualification, and to those with experience in a children's hospital.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on forms to be obtained from the undersigned, are returnable not later than 10 a.m. on Thursday, October 20th, 1938.

NICHOLAS GIBBIE, M.D.

Health Department, Medical Officer of Health,
Guildhall, Hull
October 1938.

CITY OF NOTTINGHAM. NOTTINGHAM CITY HOSPITAL.

The Nottingham City Council invite applications from duly qualified Medical Practitioners for the position of RESIDENT OBSTETRICIAN AND Gynaecological Officer at the above Hospital.

The officer appointed will be in charge of the Maternity Block and Gynaecological beds, acting under the supervision of the Consulting Obstetrician Gynaecologist, subject to the general control of the Medical Superintendent.

The salary will be £350 per annum, rising by annual increments of £25 to £450, together with usual ratings and furnished apartments. Quarters for married men are not available.

Applicants must have held a previous obstetric appointment and preference will be given to those possessing the M.C.O.G.

The successful candidate will be required to pass a medical examination and to contribute to the Corporation Superannuation Fund. The appointment is terminable by one month's notice on either side.

Forms of application together with particulars of duties, may be had from the undersigned, to whom application, with copies of not more than three recent testimonials, and endorsed "Obstetrician," should be forwarded not later than October 20th, 1938.

Gulldhall, Nottingham. J. E. RICHARDS, Town Clerk.

THE WARWICKSHIRE AND COVENTRY JOINT COMMITTEE FOR TUBERCULOSIS.

KING EDWARD VII MEMORIAL HOSPITAL.

Applications are invited for the post of JUNIOR ASSISTANT MEDICAL OFFICER (man or woman) at the Memorial Sanatorium, near Warwick, of 225 beds.

The salary will be at the rate of £250 per annum, with board, lodging, and laundry in addition, and the successful candidate will be appointed for six months.

There are three other Medical Officers at the Sanatorium.

Applications, with copies of testimonials, should be forwarded direct to the Medical Superintendent at the Sanatorium, to reach him by not later than Thursday, October 20th, 1938.

Sluire Hall, Warwick. L. EDGAR STEPHENS, Clerk of the Joint Committee.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners with appropriate qualifications for two appointments as ASSISTANT PATHOLOGIST at Group Laboratories in the Council's pathological service. Salary £650-£25-£800.

Candidates should have special experience in one or more branches of pathology in relation to the diagnosis and treatment of disease.

Forms of application and further particulars (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 2), County Hall, Westminster Bridge, S.E.1., returnable by October 31st.

Canvassing disqualifies.

COUNTY BOROUGH OF WEST HAM

EDUCATION DEPARTMENT.

Applications are invited from fully qualified Dentists (male) for appointment as SENIOR SCHOOL DENTAL OFFICER. The person appointed will be responsible to the School Medical Officer, and will be required to devote the whole of his time to the service of the Education Committee, to co-ordinate and supervise the work of the existing dental staff, and also to undertake clinical work. Salary £550 per annum, rising by annual increments of £25 to a maximum of £600 per annum, all fees received from whatever source to be paid over to the Council.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Acts and to medical examination as required by the Council for the purposes of such Acts, and the statutory contributions will be deducted from the salary.

Canvassing members of the Education Committee or the Council, either directly or indirectly, will be considered a disqualification.

Forms of application, together with particulars of duties, may be obtained from the School Medical Officer, Municipal Health Offices, 88, Romford Road, E.13, upon receipt of a stamped addressed envelope, and should be returned to the undersigned not later than Saturday, October 29th, 1938.

CHARLES E. CRANFIELD, Town Clerk and Education Officer.

Education Offices,

95, The Grove, Stratford, E.15.

October 1st, 1938.

COUNTY BOROUGH OF SOUTHEAST-ON-SEA

SOUTHEAST MUNICIPAL HOSPITAL.

The Health Committee of the Town Council invites application for the appointment of Resident Deputy Medical Superintendent at their Municipal Hospital situated at Rochford, Essex (460 Beds). Extensions to existing hospital buildings are now in course of erection. There is a staff of visiting Consultants, and the hospital is a recognized training school.

The applicants must have had experience in emergency surgery and the treatment of fractures, and previous administrative experience will be a recommendation.

Salary £500 per annum, rising by annual increments of £25 to £600 per annum, together with board, residence and laundry. Emoluments valued at £150 per annum for Superannuation purposes.

The appointment is a designated post under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Application forms to be obtained from the Medical Officer of Health, Municipal Health Centre, Warrior Square, Southend-on-Sea, and should be returned to him on or before October 19th, 1938.

Town Clerk's Office, Southend-on-Sea. H. J. WORWOOD, Town Clerk.

CITY OF PORTSMOUTH.

TEMPORARY AIR RAID PRECAUTIONS MEDICAL OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from registered medical practitioners for the post of Temporary Air Raid Precautions Medical Officer and Assistant Medical Officer of Health for a period not exceeding one year in the first place, at a salary of £500 per annum. The duties of the appointment will be whole time, under the direction of the Medical Officer of Health, and will be concerned mainly with the teaching of first aid and with the training of candidates who have had experience in Air Raid Precautions Services. Preference will be given to candidates who have had experience in first aid.

Forms of application, giving particulars of previous work and training, should be forwarded to the Medical Officer of Health, 17, Guildhall, Portsmouth, not later than 10 a.m. on Friday, October 7th, 1938.

Portsmouth. F. J. SPARKS, Town Clerk.

September 20th, 1938.

COUNTY BOROUGH OF WOLVERHAMPTON

NEW CROSS HOSPITAL.

ADDITIONAL APPOINTMENT.

Applications are invited for the post of ASSISTANT MEDICAL OFFICER (male) at the above Hospital which contains 350 beds, including Maternity, Surgical, Maternity, and Children's Wards, and a modern fully equipped.

Candidates with experience in the administration of anaesthetics and who have held previous hospital posts will be preferred.

The appointment is limited to a term not exceeding one year, with full residential emoluments, and full salary at the rate of £250 per annum, and stating age, qualifications, and experience, together with copies of three recent testimonials, should be addressed to—

A. G. ALDRIDGE, Public Assistance Officer.

Stafford Street, Wolverhampton.

Appointments for Medical Officers in the ROYAL AIR FORCE

Medical men are invited to apply for Short Service Commissions in the Royal Air Force. Candidates must be registered under the Medical Acts and be not more than 31 years of age on entry.

The period of service is 3 years—extendible to 5 years. A gratuity of £400 or £1,000 is payable at the termination of 3 or 5 years respectively. Permanent commissions are awarded in a number of cases. These offer a pensionable career with the opportunity of extra leave on full pay for specialised study. Applicants who hold—or are likely to hold—post-graduate appointments in civil hospitals may, on joining the Royal Air Force, be seconded until the termination of their appointments (for a period not exceeding one year). An antedate of commission up to twelve months is allowed for appointments held at approved hospitals.

*Fuller information can be obtained from The Director
of Medical Services, Air Ministry, Kingsway, London.*

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than November 21st, 1938.

COUNTY BOROUGH OF CROYDON.
PUBLIC HEALTH DEPARTMENT.
ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from qualified Medical Practitioners for the above appointment. Applicants must be single medical men holding a special qualification in State Medicine, or a Diploma in Public Health, and must have had three years' experience of the practice of medicine since obtaining their medical qualifications.

Preference will be given to applicants who: (a) have had experience in Infectious Diseases, and (b) who have had some experience in the Aliens' Order, 1920, and port medical work.

The candidate appointed will live at the Borough Infirmary Hospital, and will be required to undertake duties at the Croydon Aerodrome in connection with the Aliens' Order, 1920, and the Public Health (Miscellaneous) Regulations, 1938, and any other duties which may be assigned to him from time to time by the Medical Officer of Health. The candidate appointed will be required to produce a recent satisfactory medical certificate of health, and to devote the whole of his time to the duties of the office.

The salary will be £400 per annum, rising by annual increments of £25 to a maximum of £600 per annum, with board and lodging at the Borough Hospital, Purley Way, Croydon, valued at £100 per annum.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Croydon, and should be returned to him, accompanied by copies of not more than three testimonials of recent date, not later than 11 a.m. on Monday, October 17th, 1938.

I. TARNER,

Town Clerk.

September 27th, 1938

COUNTY BOROUGH OF BIRKENHEAD.
DEPARTMENT OF THE MEDICAL OFFICER OF HEALTH

BIRKENHEAD MUNICIPAL HOSPITAL.
(160 Beds.)

SENIOR RESIDENT MEDICAL OFFICER.

Applications are invited for the above appointment at the Birkenhead Municipal Hospital.

Candidates must be male, unmarried, and duly qualified registered medical practitioners. As the duties are almost entirely of a medical nature preference will be given to candidates who have obtained higher qualifications in medicine and who have had previous medical experience at either a Voluntary or Municipal Hospital.

The appointed candidate will be a member of the staff of the Medical Officer of Health.

The remuneration attached to the appointment will be £350 per annum, rising by annual increments of £25 to a maximum of £450 per annum, together with board, residence, laundry, etc.

The appointment is subject to the Local Government and Other Officers' Superannuation Act, 1922, and is determinable by three calendar months' notice on either side.

Forms of application and further particulars relating to this appointment can be obtained from Dr. D. Morley Matheson, Medical Officer of Health, 9, Hamilton Square, Birkenhead.

Conveyance, direct or indirectly, will disqualify the applicant.

Applications, endorsed "Senior Resident Medical Officer," should reach the undersigned not later than Saturday, October 22nd, 1938.

Town Hall, Birkenhead.

E. W. TAME

Town Clerk.

SWANSEA COUNTY BOROUGH.

RESIDENT MEDICAL OFFICER.

HILL HOUSE INFECTIOUS DISEASES HOSPITAL.

The Council invite applications for the above appointment from duly qualified unmarried (male) Medical Practitioners. The salary will be at the rate of £350 per annum, together with emoluments. Previous experience in an Infectious Disease Hospital is desirable. The appointment is for one year. Applications (on special forms with particulars of duties) can be obtained from the Medical Officer of Health, Public Health Offices, Swansea, to be sent in not later than Wednesday, October 19th, 1938.

A. TRINCHAM GENERAL HOSPITAL.
(100 Beds.)

Applications are invited for the posts of (1) SENIOR HOUSE SURGEON, salary at the rate of £150 per annum, and (2) JUNIOR HOUSE SURGEON, salary at the rate of £120 per annum, both with board, etc., to commence duty on or about November 6th and 12th, 1938, respectively. Applications stating age, nationality, qualifications, etc., to be addressed to the undersigned as soon as possible.

E. A. BIDEN,

Secretary.

KENT AND SUSSEX HOSPITAL, TUNBRIDGE WELLS. (210 Beds.)

Applications are invited for the post of RESIDENT SURGICAL OFFICER. Salary £250 per annum, with board, residence, and laundry in the Hospital.

The Hospital includes the following departments: Medical, Surgical, Ear, Nose and Throat, Ophthalmic, Orthopaedic, Gynaecological, Radium, X-Ray and Electro-therapeutic Massage, Pathological, Venereal Disease, etc.

In addition to the Resident Surgical Officer the Resident Staff includes:

One Senior House Surgeon.

One Casualty Officer and Junior House Surgeon.

One House Physician.

One Ear, Nose and Throat, and Ophthalmic House Surgeon.

Applications, stating qualifications, together with certificate of registration and copies of not more than three recent testimonials, should be sent to the undersigned as soon as possible. The appointment will be for twelve months.

TOM B. HARRISON,

October 4th, 1938. Superintendent-Secretary.

COVENTRY & WARWICKSHIRE HOSPITAL, Coventry. (347 Beds.)

Applications are invited for the following Resident Appointments which become vacant on November 1st next.

Application, with copies of testimonials not exceeding three in number, should reach the undersigned (from whom particulars may be obtained) on or before Tuesday, October 18th, 1938.

W. PARKES, House Governor.

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL

SURGICAL REGISTRARS. The Committee invite applications for the appointments of three Registrars (male) as from November 1st. Candidates who have obtained the F.R.C.S. (Eng.) will be preferred. Honorarium £105 per annum. The appointments are for twelve months, renewable for a further twelve months on the recommendation of the Medical Board.

Applications, with copies of three recent testimonials, should reach the Secretary, 234, Great Portland Street, London, W.1, not later than October 12th.

LONDON CHEST HOSPITAL, Victoria Park, E.2. (Bus Tram, and Rail, L.N.E.R. Cambridge Heath Station.)

The Committee of Management invite applications for the post of ASSISTANT SURGEON. An Honorarium is attached to the post.

Applications should be forwarded to the undersigned on or before October 31st, 1938.

THOMAS BROWN,
Secretary

LONDON HOSPITAL, E.1

There is a vacancy for the post of CLINICAL ASSISTANT in the X-Ray Department. Candidates must be fully qualified medically. Experience in Radiology is essential. The Honorarium of the post is £100 per annum.

Applications, with testimonials, should be sent to the House Governor, and should arrive not later than Saturday, October 22nd.

ARTHUR G. ELLIOTT,
House Governor.

KING GEORGE HOSPITAL, ILFORD

The Board of Management invite applications for the post of HONORARY SURGEON to the Hospital, a vacancy occurring on January 1st next. Applications, which may be typewritten, should be addressed to the undersigned, by whom they should be received not later than October 31st. Further particulars available upon request.

G. AUSTIN HEPPWORTH,
Secretary and Superintendent

KING'S COLLEGE HOSPITAL, London, S.E.5

Applications are invited for the post of ASSISTANT OPHTHALMIC SURGEON. Particulars may be obtained from the House Governor, to whom applications (accompanied by copies of three testimonials) should be sent not later than October 31st.

WEST LONDON HOSPITAL, HAMMER-SMITH, W.6. (239 Beds)

There is a vacancy for the newly created post of HONORARY PHYSICIAN for PSYCHOLOGICAL MEDICINE. Candidates, who may be men or women, should be Members or Fellows of the Royal College of Physicians, and should have had some experience in Child Psychiatry. A Diploma in Psychological Medicine is desirable. The candidate appointed would be expected to undertake at least one Out-Patient Session per week and such teaching as may be required by the Medical School. The appointment does not carry with it the charge of any Hospital beds.

Applications, accompanied by copies of testimonials, must reach me by first post on Thursday, October 20th. Candidates must attend a meeting of the Medical Council at 4.30 p.m. on Friday, October 21st, and prior to that date call upon and send copies of their application and testimonials to each member thereof. They must not canvass members of the Board, but, nevertheless, must send copies of their application and testimonials to each member thereof and, if so notified, be in attendance at a meeting of the Board at 5 p.m. on Tuesday, October 25th, when the appointment will be made.

H. A. MADGE, Secretary.

WEST LONDON HOSPITAL, HAMMER-SMITH, W.6. (239 Beds.)

An additional HONORARY REGISTRAR is required for the Throat, Nose, and Ear Department. The appointment is for one year from November 1st next and, subject to annual re-election, may be extended for a period of not longer than three years.

Applicants must be duly qualified registered Medical Practitioners with previous experience in otolaryngology.

Applications, accompanied by copies of testimonials, must reach me not later than Thursday, October 20th, first post. Candidates must attend a meeting of the Medical Council at 4.30 p.m. on Friday, October 21st, and, prior to that date, call upon and send copies of their application and testimonials to each member thereof. They must not canvass members of the Board but, nevertheless, must send copies of their application and testimonials to each member thereof and, if so notified, be in attendance at a meeting of the Board at 5 p.m. on Tuesday, October 25th, when the appointment will be made.

H. A. MADGE,
Secretary.

WEST LONDON HOSPITAL, Hammersmith, W.6. (239 Beds.)

CHIEF ASSISTANT to the Department for TREATMENT OF INJURIES required. The post is a resident one and the duties commence on November 1st. Salary at the rate of £200 a year, with board and lodging. Candidates must be duly qualified registered Medical Practitioners, and it is desirable that they should possess one of the higher Surgical Degrees or Diplomas. They must have had special experience in the treatment of fractures.

The appointment will be terminable by a month's notice on either side, will be for a period of six months in the first instance, but this period may be extended.

Applications, which must be made on printed forms obtained from me, must reach me not later than the first post on Thursday, October 20th. Candidates will be required to call upon such members of the Medical Staff as directed: to be in attendance at a Medical Council Meeting at 4.30 p.m. on Friday, October 28th, and the House Committee Meeting at 5 p.m. the same day, when the appointment will be made.

H. A. MADGE, Secretary.

THE QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2, (204 Beds.)

The Board of Management invite applications for the post of EAR, NOSE AND THROAT SURGEON. Candidates must be Fellows of the Royal College of Surgeons of England or of another recognized College. Attendance required, two half-days weekly. The appointed candidate will have charge of beds.

An honorarium to cover travelling expenses will be paid.

Further information may be obtained from the undersigned, to whom applications, with copies of three recent testimonials, should be sent not later than October 12th, 1938.

CHARLES H. BESSELL,
Secretary.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.1.

Applications are invited for the post of HOUSE PHYSICIAN (male) for six months (first two months in the Casualty and Out-patient Department). Salary at the rate of £120 per annum, with board and residence.

Applications, with copies of three recent testimonials, should be sent at once to the undersigned, from whom particulars can be obtained.

W. H. SIDNELL, House Governor.

FINSBURY DISPENSARY, FRIEND STREET, LONDON, E.C.1.

Applications are invited for the posts of RESIDENT and ASSISTANT RESIDENT MEDICAL OFFICERS (Ladies).

Duties will consist of attending patients at the Dispensary and home visiting. The Officers appointed will not be allowed to engage in private practice, but may lecture or pursue research work on condition that such work does not clash with their duties. Salaries at the rate of £250 and £200 per annum respectively. Turned-out apartments provided and a joint grant at the rate of £10 per annum made towards cost of employing servant, laundry, fuel, gas, and lighting.

Preferential consideration would be given to ladies who have been accustomed to working together.

Applications, stating age, qualifications, experience, and accompanied by copies of three recent testimonials, should reach the undersigned promptly.

ARTHUR W. PRIOR,
Secretary.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road, W.C.1.

LONDON, S.E.—PARTNERSHIP.—ONE-HALF SHARE in well-established good mixed Practice, producing approximately £2,600 p.a., including panel of about 1,900. Fees from 1/6. Suitable house available with 5 bedrooms, etc. Premium 2 years' purchase. Incoming partner must be experienced and energetic worker.

LONDON, S.W.—CENTRAL DISTRICT.—Recently established better-class non-dispensing PRACTICE, with scope for OPHTHALMOLOGY producing nearly £1,200 p.a., of which about £200 is derived from refractions. Fees 10s. 6d. to 21s. House contains 2 reception, 6 bedrooms and Professional rooms. Price, leasehold £950 p.a. Premium £1,500, part by arrangement.

MANCHESTER.—Very old-established middle- and working-class PRACTICE averaging for last 3 years £1,350 p.a. Panel of 840. Appointments about £180 p.a. Fees from 3/6. House with 3 bedrooms, etc., garden, garage, electric light. Price freehold £240. Premium for quick sale, 11 years' purchase, part by instalments.

LONDON, EAST.—Old-established mixed-class PRACTICE averaging about £2,700 p.a., including panel of about 1,300, and increasing. Separate surgery premises. Premium 2 years' purchase.

LONDON, N.W.—GROWING RESIDENTIAL DISTRICT.—PARTNERSHIP.—Guaranteed share, in rapidly expanding Practice producing about £1,800 p.a., with increase later. Suitable detached house on rental at £52 p.a. Incoming partner must be experienced and energetic.

KENT.—RAPIDLY EXPANDING DISTRICT.—Well-established middle- and working-class PRACTICE, producing about £1,700 p.a., including panel of nearly 1,400. Bedrooms, etc., large garden. Inclusive rent £1,000.

MIDDLESEX.—DEVELOPING AREA.—Well-established mixed-class PRACTICE averaging over £1,500 p.a., including panel of 880 and appointments worth about £100 p.a. Corner house with 2 reception, 4 bedrooms, etc., garden, garage. Rent £100 p.a. Premium £2,000 or near offer for quick sale.

KENT COAST.—PARTNERSHIP.—ONE-THIRD OR ONE-HALF SHARE in middle-class Practice averaging £3,650 p.a. Panel of about 2,000. Excellent modern house available by purchase or rental. Premium 2 years' purchase. Incoming partner must be experienced and well qualified.

YORKS.—COUNTRY PRACTICE.—Old-established, income about £1,030 p.a., with scope for increase. About £350 of present income is derived from panel of some 500 patients. Good freehold house with ample accommodation, garden and garage. Price for practice and house £3,600 of which about £1,900 may be left on mortgage.

GLOS.—NEAR WYE VALLEY.—Very sound PRACTICE producing about £1,300 p.a., including panel of 1,150 patients and appointments worth about £80 p.a. Low expenses. Detached house with large garden, 5 bedrooms, etc. Freehold. Premium 11 years' purchase.

FAVOURITE SOUTH COAST RESORT.—Private and better-class PRACTICE averaging over £1,000 p.a. Minimum fee 5/6. No dispensing. Scope for panel if desired. Modernized house with ample accommodation. Premium £1,000.

ESSEX.—PARTNERSHIP after ASSISTANTSHIP of 3 months in chiefly better-class Practice producing about £1,500 p.a. Good house available on rental. Share worth £1,000.

WEST LONDON.—Old-established chiefly upper- and middle-class PRACTICE averaging approximately £1,500 p.a. Selected panel of 114 patients, but scope for increase if wished. Fees 5/6 to 21s. Non-dispensing. Scope for increase at large blocks of modern flats in course of erection. Excellent house with ample accommodation. Premium £3,000.

MIDLANDS.—GOOD RESIDENTIAL COUNTRY DISTRICT.—Complete PRACTICE at present producing about £750 p.a., but capable of considerable expansion. Choice of 2 houses. Moderate premium for quick sale. Vendor retiring through ill-health.

OUTLYING NORTHERN SUBURB.—Recently established PRACTICE on new estate producing about £300 p.a., including panel of 350. House with 2 reception, 3 bedrooms, etc. Garden. Price £670. Reasonable premium accepted.

NORTH-WEST LONDON.—PARTNERSHIP.—One-fifth share (with increase later) in well-established Practice producing about £5,200 p.a., including panel of about 600. Suitable maisonette with 2 reception, 2 bedrooms, etc. Inclusive rental £90 p.a. Premium 2 years' purchase.

DURHAM COUNTY.—Old-established industrial PRACTICE producing £2,000 p.a., of which only about £450 is derived from private work. Panel of over 2,100 units. Practice has been held by the vendor for about 20 years. Premium £4,000 to include book debts, drugs, surgery furniture, etc. (part by arrangement), or £3,600 cash down.

COAST TOWN, WITHIN 80 MILES OF LONDON.—Well-established PRACTICE producing about £1,600 p.a., of which about £1,100 p.a. is derived from panel of approximately 1,300 patients, P.M.S., etc. Good heating. Ample scope for increase. Thoroughly modernized and redecorated, central heating. Price £1,800. Premium 2 years' purchase.

DEVON COAST RESORT.—Old-established non-dispensing PRACTICE averaging for the past 3 years £1,640 p.a., including panel of 400. Suitable house with ample accommodation. Freehold £1,100 or would rent. Premium £2,800.

WEST MIDDLESEX.—Well-established mixed-class Practice having exceptionally £2,000 p.a., including panel of £1,100 p.a. and P.M.S. £450 p.a. Approximate 3/6. Suitable house with 2 reception, 4 bedrooms, etc., garden, garage, light. Rent about £70 p.a. Must be experienced, preliminary assistantship.

ASSISTANTS REQUIRED.—Several good vacancies. Full details on application.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

AMPOULES.

TABLETS.

SUPPOSITORIES.

EUPHYLLIN dilates the Coronary and Kidney Vessels, greatly increases the rate of flow of blood through the heart, and improves the mechanism of exchange between the blood and the tissues.

EUPHYLLIN is particularly suited to the treatment of CORONARY SCLEROSIS, ANGINA PECTORIS, and DEGENERATION OF THE CARDIAC MUSCLE.

Special literature and samples will be forwarded on request.

NUTRITIONAL ANÆMIA in INFANCY

THE prevalence of Anæmia in Infancy is more widespread than is popularly believed (Med. Research Report No. 157, H. M. M. Mackay). In these extensive investigations, treatment by iron dosage was demonstrated as being the most effective—particularly in the vehicle of a Milk Food. In the form of

In addition to its value in the treatment of Nutritional Anæmia, Hēmolac has been shown to act as a prophylactic against the common catarrhal infections of the respiratory and alimentary tracts.

Clinical samples and literature will gladly be sent to any member of the Medical or Nursing Professions.

HĒMOLAC^{REGD}

(Full Cream Milk Powder with Iron Ammonium Citrate)

the dosage of iron is assured and graduated for weight and age.

NEW!—Reimann on Pneumonias

Just Off Press—Here are the *latest clinical facts* on more than 50 forms of Pneumonia—facts that have been correlated, organised and presented by Dr. Hobart A. Reimann, Professor of Medicine in Jefferson Medical College, Philadelphia.

Dr. Reimann's approach is aetiological and follows to-day's accepted classification of the pneumonias. Throughout the book the author gives full details on causes, incidence, virulence, immunity, predisposing factors, pathogenesis, preventive measures, symptoms, etc. *Diagnosis* is given *special* attention and includes full details on physical signs and their meaning, on clinical and bacteriological methods, and on typing methods. Important facts are stressed throughout the course of the disease.

Above everything else this *new book* will be valued for the practical up-to-date help it gives on *Treatment*—supportive treatment, diet, treatment of specific conditions such as cough, thoracic pain, abdominal distention, anoxaemia and cyanosis, use of artificial pneumothorax, specific immune serum, chemotherapy, convalescent serum, prevention and treatment of complications, etc.

103 pages are devoted to Lobar Pneumonia. There is a separate chapter on Pneumococcus Pneumonia in Infancy and Childhood, five chapters on Atypical Pneumonia, an entire section on Pneumonia Occurring as Part of Systemic Disease, and finally, a discussion of the Secondary Pneumonias, including postoperative pneumonia. Case histories, in brief, are given under the illustrations.

By HOBART A. REIMANN, M.D., Professor of Medicine, Jefferson Medical College. With a Foreword by ELLIS CULL. Octavo of 381 pages, illustrated. Cloth, 25s. net.

NEW! Beck's Laboratory Manual of Haematological Technique

Just Off Press—This *new manual* is based on the author's own wide laboratory experience and on more than *350,000 laboratory tests*.

Dr. Beck explains fully the technique of procuring blood specimens, the clotting mechanism, and estimation of haemoglobin. There is an entire section on enumeration of cells, and determination of indexes, including especially detailed directions for determining normal standards.

It takes up the study of the cell including origin, staining, and making cell counts. It devotes *82 pages to special studies used in haematology*, including the latest technique for typing and matching blood, and the book concludes with a section on *special blood pathology* in which there are individual chapters dealing with the blood findings in infants and children, the effect on the blood picture of chemicals, radioactive substances and splenectomy, and other important and helpful laboratory diagnostic facts.

By REGINA COOK BECK, M.A., M.D., Head of the Department of Bacteriology, William and Mary College Extension. With a Foreword by FRANK W. KONZELMANN, M.D., Professor of Clinical Pathology, Temple University. Octavo of 389 pages, illustrated. Cloth, 13s. net.

NEW! Mallory's Pathological Technique

Just Ready!—The medical technician, pathologist and physician alike will find this *entirely new book* by Dr. Frank B. Mallory an especially worthwhile addition to their everyday working libraries. Here, indeed, is a concise, compact, but unusually thorough presentation of *pathological techniques and their application in diagnosis*.

Dr. Mallory has divided his book into three sections: General Materials and Histological Methods; Special Histological Methods; and Autopsy Methods. There is an extensive consideration of the circulatory system, blood, bone marrow, lymph nodes, spleen, respiratory system, excretory system, reproductive system and other organs and systems of special importance, while an entire chapter is devoted to infectious agents. Dr. Mallory has included a *75-page section on Pastmartem technique*. And in addition to all this there is a chapter on preservation of specimens and still another on gross and micro-photography.

By FRANK BURN MALLORY, A.M., M.D., S.D., Consulting Pathologist to the Boston City Hospital. Octavo of 434 pages, illustrated. Cloth, 20s. net.

New Wolseley cars give

not merely **more mileage** but **more**

power per pint of petrol

OF WHAT ADVANTAGE is petrol economy if it means a half-starved, sluggish engine? The new "power-plus-economy" cylinder head technique developed in the new Wolseley cars takes full advantage of modern improvements in petroleum technology and provides a new conception of acceleration and sustained speed together with a great advance in cruising economy. Wolseley cars give you more power per pint of petrol. And with added power comes the ability to use it to its full advantage on the road. "Phased Suspension" gives to all models complete freedom from rolling and pitching

as well as those phenomenal road-holding qualities which permit fast "point-to-point" averages.

And speed in a Wolseley is speed in comfort. Clever bodywork has still further increased accommodation both for the 5 occupants and their full complement of luggage. Improved sound insulation and fresh air control, finger-light controls instantly to hand, the exclusive Wolseley night-pass lighting system all contribute to make these new models the most luxurious and easy-to-handle cars in their respective classes.

The Hearing Aid of Excellence

BONOCHORD P.3

Vest Pocket Valve Amplifier

SMALL AS A MICROTELEPHONE, YET WITH THE HIGHEST OUTPUT EVER OBTAINED FROM A POCKET VALVE DEAF AID.

Since their introduction the main obstacle to the general use of valve amplified deaf aids has been their bulk and weight. Attempts have been made to produce them in a form suitable for wear on the person without inconvenience, but in every case performance has been sacrificed to size, or the instrument has been ungainly for pocket use.

The BONOCHORD P3 is a 3 valve amplifier with piezo-electric microphone, which will fit easily into a waistcoat pocket, with separate batteries. Special valves designed for us have made this possible, together with the use of small components developed by our Research Department. In spite of its small size the aid has the amazingly high maximum output of 60 decibels. Let us send you full details of this new instrument, which we believe will do much to establish the general use of valve aids.

AN OPEN INVITATION

*Radio-Microphone Hearing Aid
offered for clinical test*

IN making the Maxade Hearing Aid for deaf persons, we have successfully applied the knowledge gained in 20 years' radio and acoustical experience. We believe and know that our radio crystal-microphone models with midget-valve amplifiers will undoubtedly enable aurists to remedy or relieve their patients' deafness. Leading hospitals and clinics have acknowledged the merit of Maxade by consistent recommendation and Maxade is entered upon the Approved list of the National Institute for the Deaf.

Confidently, therefore, we cordially invite practitioners to subject any of our models to a free practical test—as an enlightening demonstration of the efficiency, natural tone, compactness and simplicity which place Maxade so far ahead. Pocket and other portable types are available at moderate prices on convenient payment terms. Full details on application to Managing Director, W. Scott Worthington, F.R.S.A., Peto Scott Co., Ltd. (Est. 1919), 77, City Road, London, E.C. 1.

HOMOGENISATION of Fruits & Vegetables

The process of homogenisation applied to fruits, vegetables and soup does far more than commercial or home "straining" can achieve. It actually breaks down the cell-walls of the foods, so that besides releasing more nourishment, it renders them harmless to the most delicate infant digestive system. Nestlé's Homogenised Foods are of such a milk-like consistency that they can be given in the bottle with the milk if necessary, and enable the administration of valuable fruits and vegetables to infants even of four months. An interesting Booklet about recent research into the homogenisation of fruits and vegetables is now ready, and will be sent on receipt of the coupon, together with gratis supplies for your own clinical testing.

Photo-micrograph of stool of normal baby fed on commercially-strained vegetables.

Stool of normal baby fed on Nestlé's Homogenised Vegetables.

ABDOMINAL DISTENSION, PARALYTIC ILEUS treated with **'DORYL'** MERCK

In addition to its action on the bladder, 'DORYL' also promotes intestinal tone and motility, and has been found of value in treating the severe symptoms of post-operative abdominal distension, paralytic ileus, etc.

The bowel effect of 'Doryl' in some patients treated for retention of urine has been noted ("The Lancet," Jan. 30th, 1937), and it is confirmed that it is being used in cases of distension after operation in some hospitals as a routine measure ("B.M.J.," June 18th, 1938).

AN IMPORTANT ADVANCE IN

Menstrual Hygiene

TAMPAX

SANITARY PROTECTION WORN INTERNALLY

Expanded Tampax in situ showing adaptation to the vaginal walls and distance from urethral orifice.

The principle of this new method of sanitary protection is that of the vaginal tampon. The menstrual fluids are taken up at the site by the highly absorbent, long-fibred surgical cotton-wool of which Tampax is composed. Each tampon has an absorption capacity of 1 to 1½ ounces. A patented sealed applicator enables the user to insert Tampax in the proper position without contact with the hands and a patented stitching process makes disintegration impossible and

ensures complete removal.

Dispensing thus with sanitary towels,

Tampax provides relief from physical and mental discomfort, and confers freedom and peace of

mind. Tampax may confidently be recommended by physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymeneal aperture would cause difficulty in insertion and withdrawal.

We will be glad to send to doctors a full-size package of Tampax together with fuller details on request to Tampax Ltd., 10, Bolton Street, London, W.1.

TAMPAX

Regd. Trade Mark.

ALASIL

Safe Salicylate Therapy

THE popularity of acetyl-salicylic acid is undoubtedly due to the fact that it is one of the safest and most effective non-narcotic analgesics available. Too often, however, its use has been discarded by the physician on account of its tendency to irritate the stomach and because entirely pure preparations are not always available.

"Alasil" provides the beneficial therapeutic effects of pure acetyl-salicylic acid in such a form that it is acceptable even by disordered digestions. This tolerability is due to the fact that it combines calcium acetyl-salicylate—the least irritating salicylate compound—with "Alocol," a potent gastric sedative and antacid.

Since "Alasil" is better tolerated than acetyl-salicylic acid its use can be pushed or prolonged to a much greater extent than the latter. "Alasil" is, therefore, an analgesic antipyretic and anti-rheumatic which can be employed with complete confidence in all the many conditions in which such an agent is indicated.

★ NOW AVAILABLE TO THE
MEDICAL PROFESSION

HESPERIDIN TABLETS G.L.

(Vitamin P)

Associated with vitamin C in nature is found hesperidin—a flavone compound named "vitamin P" by Szent-Gyorgyi (Nature, 1936, 138.27).

Hesperidin is claimed to regulate vascular permeability: it appears to be effective in conditions involving increased permeability or fragility of the capillary wall.

Glaxo Laboratories Ltd. are now ready to supply tablets of hesperidin in standardised form for convenient administration. Each Hesperidin Tablet G.L. contains the equivalent of 0.25 gm. of the compound. The tablets are uncoated and without taste. Up to four tablets daily have been given with success.

IN BOTTLES OF
50 TABLETS 5/6.

This Price (not applicable in Eire) is subject to usual professional discount.

PRODUCT OF THE
GLAXO LABORATORIES

A report by two British investigators (Lancet, 1938, 2, 610) demonstrates that hesperidin can reduce the number of spontaneous and induced petechial haemorrhages in patients exhibiting general vitamin deficiency. The effect appears to be independent of the presence of vitamin C. The hesperidin, supplied for the trials by Glaxo Laboratories Ltd., was administered orally in doses of 1.0 gm. daily or less.

Hesperidin is clearly a dietary substance of some importance. It remains for further work to indicate its value and scope in clinical practice.

**To be shown for the first time at the London Medical Exhibition (Oct. 17th-21st). Stands No. 95, 96 and 109.*

EFFICIENT

Oral ANTISEPSIS

demands HIGH GERMICIDAL
EFFICIENCY *plus* STABILITY
plus SAFETY

Regular gargling or spraying of the throat with an antiseptic is recognised as a valuable prophylactic measure against common winter ailments. For this important work, the selected antiseptic should possess certain 'plus' characteristics, in addition to efficient bactericidal action. Stability in the presence of saliva, mucus, blood and pus, and absence of caustic or irritant action are two vital additional properties, without which successful oral antiseptics is impossible.

T.C.P. is indeed a 'plus' antiseptic, it combines the highest bactericidal efficiency with complete stability in the presence of organic matter. T.C.P. cannot harm or irritate the most sensitive tissues.

One other 'plus' feature—T.C.P. exerts a marked analgesic action, a grateful refinement in the treatment of painful inflammatory conditions of the throat.

To establish a strong positive Iron Balance

Idozan contains 5 per cent. assimilable iron. It is non-constipating and acts in fact as a mild aperient. Idozan is a neutral solution, and exerts no harmful effect on the teeth. A tablespoonful three times a day provides the patient with a daily intake of 2.25 grams of pure iron, and thus establishes, without contra indications, a strong positive iron balance.

Idozan is now made in England, and is regularly prescribed by doctors in no less than fifteen different countries.

IDOZAN

The most extensively prescribed iron preparation in the World.

Packings: 4 oz., 8 oz., 40 oz., and 80 oz. bottles.

MARMITE

YEAST EXTRACT
for Vitamin B complex
in POLYNEURITIS

The close connection between polyneuritis and vitamin B₁ deficiency is well known. Not only is the polyneuritis of beri-beri considered to be due to deficiency of this factor, but so also is the polyneuritis associated with gastro-intestinal lesions, pregnancy, alcoholism and other toxic conditions.

Clinical tests have proved beyond doubt that Marmite therapy is effective in these cases of polyneuritis of nutritional origin. In a recent paper on peripheral neuritis, associated with pyloric stenosis and deficiency of vitamin B₁, it is recorded that the patient

"was advised to take Marmite, 2 drachms daily . . . made a gradual improvement and returned to work . . . still takes Marmite. . ."

(Lancet, May 7th, 1938, p. 1045.)

VITAMIN B₁ IN FOODS

Biochemical J., 1935, and other sources

BEMAX

The figures represent International Units per ounce.

"The grain products are the backbone of the nutrition of most races of the earth. As a rule they are our cheapest food fuel."

from "YOUR DIET AND YOUR HEALTH"

BREAD

... for energy

"Vitamin B₁ deficiency an outstanding fault in the diet of many millions of people"

(B.M.J., 16 Oct., 1937, p. 753)

The reduction in Vitamin B₁ intake, due to changes in dietary habits during the last hundred years, normally amounts to at least 50 per cent., and may be as much as 70 per cent. It has been demonstrated, both experimentally and clinically, that a shortage of Vitamin B acts as a limiting factor in the maintenance of health and nutrition, and often results in gastro-intestinal disorders, loss of appetite, indigestion, constipation and, if long continued, to neuritis and arthritis.

The logical way to rectify such shortage is to restore to the diet the Vitamin B-containing substance whose removal is responsible for the deficiency.

This substance is available in the form of Bemax.

For years it has been the policy of the proprietors of Bemax to ensure its Vitamin B₁ activity by biological assay of every day's output. So far as is known, Bemax is the only food product for which such a claim is or can be made.

The quantity of Vitamin B₁ supplied by the normal daily dose of Bemax—one tablespoonful—is 200 International Units, an amount sufficient to raise a deficient diet to an optimal level.

The normal daily dose of Bemax supplies, in addition to Vitamin B₁, significant quantities of Vitamin B₂ and B₆, Copper, Iron and Phosphorus as well as rich quantities of Vitamin E and other essential dietary elements.

Bemax is an entirely natural product consisting only of stabilised wheat germs selected for their Vitamin B₁ activity with no addition whatsoever. Clinical sample and literature on request. Vitamins Ltd., The Bemax Laboratories (Dept. B.69), 23, Upper Mall, Hammersmith, W.6.

Sterility and Habitual Abortion

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertiol.

*'... a very decided help especially in inflammatory
diseases of the lungs... I believe if it is used early it
will abort potential pneumonia cases' --- M.B. B.Ch.*

For more than a decade S.U.P. 36 has been employed with striking success for the control of inflammatory diseases of the respiratory system, and its use in every-day clinical practice for the treatment of influenza and pneumonia is now an established routine.

The administration of S.U.P. 36 has produced a satisfactory response in many other conditions in which pyrexia is an outstanding symptom. S.U.P. 36 is available in sterile solution in ampoules ready for intramuscular injection.

The use of the

B.D.H. GONADOTROPIC HORMONES

in the male

SEROGAN AND GONAN

Of the two B.D.H. gonadotropic hormones, Serogan and Gonan, Serogan stimulates the germinal epithelium of the testis, leading to active spermatogenesis; Gonan, on the other hand, acts primarily upon the interstitial cells and connective tissue, leading to increase in size of the testis, marked internal secretory activity and added mobility of the undescended organ.

Serogan is thus indicated in the treatment of impotence and sterility in the male, and Gonan in the treatment of undescended testes.

SEROGAN in the Treatment of Impotence and Sterility in the male

One ampoule of Serogan 200 R.U. (in resistant cases 1000 R.U.) should be administered by intramuscular injection twice weekly.

The length of treatment required depends, of course, upon the severity of the case, but carefully-controlled sperm-counts have shown that improvement may be expected in the majority of cases at the end of six to eight weeks' treatment.

GONAN in the Treatment of Undescended Testes

In the true cryptorchid in whom the testes are retained in the abdomen an injection of Gonan 500 R.U. intramuscularly is given twice weekly. In less severe cases, such as uncomplicated cases of canal-dwelling testis, the injections may be given once weekly.

GLOBULIN **Lederle** MODIFIED

ANTITOXIN

THE GLOBULIN-MODIFIED *Lederle* technique, embodying the principle of peptic digestion, is the only practical procedure which permits such a high degree of concentration of antitoxin and reduction in the amount of troublesome proteins—the cause of serum reactions.

That is why Globulin Modified Antitoxins *Lederle* represent

- a reduction in the expected incidence and severity of serum disease;
- less inconvenience to the patient;
- a greater ease of administration;
- a greater potency per c.c.

DIPHTHERIA ANTITOXIN *Lederle* as prepared by the Globulin Modified Technique contains 6,000 to 7,000 units per c.c., except in the lower unitages where the volume is adjusted to facilitate ease of handling. A concentration which we believe has never been previously attained with commercially available antitoxins.

Since Diphtheria Antitoxin absorbs circulating toxins and checks the further spread of the toxæmia, prognosis is largely dictated by the promptness by which adequate dosage is injected and the route by which it is given.

The improved and refined *Lederle* product permits of the administration of large dosage in small bulk by the intravenous route without the fear of untoward reactions.

INDICATIONS FOR 'SANATOGEN'.

No. 17

FATIGUE IN CHILDHOOD

"I'm so tired!"

The Emeritus Professor of Diseases of Children at King's College Hospital has just written an interesting book on "Common Happenings in Childhood". One of his chapters begins with the words: "I'm so tired". The author points out that apart from the natural fatigue which vigorous exercise induces there is a morbid tiredness which is "unnatural". Examining the first hundred cases in his note book in which "tiredness" figures as a prominent symptom, this physician finds that nearly one-half of the children presented signs of faulty digestion.

Two factors presumably contributed to the pathologic state of these children—faulty absorption of essential food elements, and incomplete elimination of waste with consequent retention of toxic products. He concludes that in these cases there is some degree of starvation, and that the tissues consequently have less to draw upon for their "recuperation from the changes induced in them by fatigue".

When this symptom presents itself, 'SANATOGEN' has often been found of great value owing to its high protein and phosphorus content and its ready assimilability. 'SANATOGEN', containing 95 per cent. milk casein with 5 per cent. glycerophosphate of soda, is rapidly absorbed and utilised. It is non-irritative, and, in addition to its high nutritive value, it stimulates gastric functioning, increases appetite and promotes the digestion and absorption of other foods taken with it.

"I have found 'SANATOGEN' a most useful restorative after severe illness, childbirth, etc., and also in debilitated children."

—M.R.C.S., L.R.C.P.

"As for 'SANATOGEN', I have been using it for almost 30 years and ordered it with satisfaction in innumerable conditions. For non-thriving young children I think it is an excellent tonic."

—M.D., Ch.B., M.B.

"I could not bring about any improvement in a young girl I was attending. She was about fourteen years old, over six feet in height, thin and listless. In fact, the usual type who had 'outgrown her strength'. Her mother stated that she would never go out without her or with others of her age, liked school but dreaded going. In fact, she was so self-conscious that she was getting morbid. I tried the usual tonics but no improvement. I then prescribed 'SANATOGEN', and in a very short time there was marked improvement. The girl is now going about enjoying life like her contemporaries. Undoubtedly 'SANATOGEN' deserves all the credit for her remarkable improvement."—M.D.

'SANATOGEN'

(Trade Mark)

A brand of Casein and Sodium Glycerophosphate

Sold by all chemists price 2/3 to 19/9

DOSAGE: For children and adults two teaspoonful three times daily, or according to circumstances. For infants 2 teaspoonful added to each bottle feed.

The word 'SANATOGEN' is the Trade Mark of Genatosan Ltd. and denotes their famous brand of Casein and Sodium Glycerophosphate. A 'GENATOSAN' product made by GENATOSAN Ltd., Loughborough, Leicestershire.

Clinical samples and literature available on request to

GENATOSAN LTD., LOUGHBOROUGH, LEICESTERSHIRE

THE ADVANTAGES OF COD LIVER OIL

as a source of

VITAMIN A and VITAMIN D

In view of the widely varying vitamin content of many liver oils available to the public, it is interesting to note that the British Pharmacopoeia in their most recent Addendum (1936) lay down a definite standard of vitamin content for cod liver oil, and also a definite dosage.

The vitamin content is standardised at not less than 600 International Units of Vitamin A and not less than 85 International Units of Vitamin D per gramme; and the dosage is given as a minimum of 15 minims (a quarter teaspoonful) three times a day. The oil itself is described as "from the fresh liver of the cod."

'SevenSeaS' Cod Liver Oil is extracted on the boat, within thirty minutes of the fish being taken from the sea. It is therefore fresh and easily digested. It is an interesting point of fact that the process of extraction on the boat is impossible with other fish liver oils. 'SevenSeaS' therefore obviates any need to resort to liver oils made from stale and rancid livers.

In its Standard form, 'SevenSeaS' is guaranteed to conform to the standard

vitamin content laid down by the British Pharmacopoeia. For practitioners wishing to administer Vitamin A and Vitamin D in cases where a large fat intake is contra-indicated, 'SevenSeaS' in its 'High Potency' form has a special significance. The vitamin content of this 'High Potency' oil is guaranteed to be four times the Pharmacopoeia standard, and the dosage can therefore be reduced to a few drops only. This is not a fortified oil, but is obtained simply by selection from the oils of the richest livers.

All 'SevenSeaS' Cod Liver Oil is tested and packed in strict conformity with British Pharmacopoeia requirements. Samples of the High Potency Oil, the Standard Oil, and the High Potency Oil in Capsules, will be supplied on request.

VEGETABLE PURÉES IN PEDIATRICS

A solution to the problem of home preparation

THE markedly improved nutrition and successful tolerance by infants to strained vegetables and fruits is rapidly securing a universal popularity for this dietary.

In theory there is no more desirable way of meeting systemic acidity, nutritional anaemia and supplying dietary bulk for intestinal residue in a non-irritant form.

In practice, however, defects in the home preparation of purées retard or defeat the end in view. The vegetables used are not fresh, overmuch water or boiling in uncovered kettles reduces the mineral and vitamin content, and coarse sieving allows harsh fibre to pass.

In consequence there is a growing demand on the part of physicians and mothers for such a product that shall have the highest possible nutritive value, and complete uniformity. Their attention having been drawn to this, the H. J. Heinz Company decided that here was a legitimate extension of their services in view of their wide buying resources and long experience in the preparation of foods.

This company is accustomed to buying vegetables in those regions where they grow best, and to dealing with them within a few hours of their harvesting at the correct season of the

year. This last is, of course, highly important.

The best factory practice is inevitably better than home preparation, however careful. After scrupulous cleaning, for example, vegetables are cooked in the Heinz factories under light steam pressure with exclusion of air until just soft enough to be comminuted by extrusion and cutting. The whole process is so regulated that the juices of the vegetables are retained throughout, there are no mechanical losses of mineral salts, vitamins or other soluble nutrients, and the resulting purée is adjusted to the proper consistency for satisfactory marketing.

Before filling and sealing, the product is subjected to a process for the removal of any absorbed air, and sealing takes place *in vacuo*. Finally, the sealed containers are immediately sterilised under known conditions of time and temperature. By these means are secured the high nutritional qualities, uniformity and convenience that physician, mother and patient desire.

THROUGHOUT THE SPAN

The problem of treatment in intestinal stasis is definitely settled in the minds of those thousands of physicians who depend on Agarol.

Agarol is a readily miscible emulsion of high-grade mineral oil and agar-agar with phenolphthalein. Free from alcohol, alkali and sugar, it is suitable for use in every condition where an evacuant is indicated and at every age period.

The palatability of Agarol appeals to all. In appropriate doses it is mild enough for infants, yet active enough for the demands of adult age.

Supplied in 4½ oz.,
7½ oz. and 17 oz.
bottles.

•
The average adult
dose is one table-
spoonful.

•
Agarol is not adver-
tised to the public.

AGAROL
BRAND COMPOUND
FOR CONSTIPATION

Similar names—but dissimilar properties

In scope and character 'Benzedrine' Brand Tablets and 'Benzedrine' Brand Inhaler are completely different

'BENZEDRINE' BRAND TABLETS

Restricted

These tablets contain the SULPHATE of β -aminoisopropylbenzene (5 mg.) and are administered orally.

On and after January 1, 1939, they can be supplied only on the written authority of a registered medical practitioner or on the signing of the Poisons Register.

'Benzedrine' Brand Tablets have a striking effect in stimulating the central nervous system and have proved of value in narcolepsy, post-encephalitic Parkinsonism, depressive and asthenic states, impaired mental efficiency, and gastro-intestinal spasm.

'BENZEDRINE' BRAND INHALER

Exempt from all control

'Benzedrine' Brand Inhaler consists of an aluminium tube packed with VOLATILE β -aminoisopropylbenzene, which possesses a decongestive potency greater than that of ephedrine.

After careful examination, this Inhaler has been totally and authoritatively exempted from all restrictions of sale by the Poisons (Amendment) Rules, 1938. It is perfectly safe, even for young children, and is indicated for shrinking the nasal mucosa in head colds, sinusitis, nasal catarrh, hay fever, and asthma.

Detailed literature concerning both these preparations is available on request.

Simplify the Technique of Infant Feeding by using Allenburys Progressive System

ALLENBURYS SYSTEM EMBODIES THE FOLLOWING
ADVANCES IN THE SCIENCE OF INFANT FEEDING

- (1) Humanised Casein : lactalbumen ratio.
- (2) Intimate incorporation of Dextrin-Maltose, the benign starch-free mixture of non-fermenting carbohydrates.
- (3) Homogenised Cream in reconstituted Milk Foods.
- (4) Prophylaxis of Scurvy. Every tin of Allenburys Foods bears, and has borne in the past, explicit instructions for daily administration of vitamin C.
- (5) Prophylaxis of Rickets. Calcium : Phosphorus ratio adjusted. 560 units of vitamin D per quart reconstituted. Independent biological assay of antirachitic potency.
- (6) Prophylaxis of Anæmia. The reconstituted foods contain 4 parts per million of available iron.

Allenburys System provides every known Nutritional Requirement of the Infant
It enables the physician to replace unreliable home-made milk mixtures with readily prepared infant foods which eliminate the risk of enteral infection, and provide easily digested, scientifically balanced meals for babies at every stage in their development.

ALLENBURYS Humanised MILK FOOD No. 1 (Entirely Free from Starch)

The best first artificial food because it resembles breast milk closely in composition and in the ease with which it is digested.

| Composition when reconstituted by dilution (1-6) with water as instructed on tins: | | | | | | | | | |
|--|--------|-------------|---------|---------|---------|-------|-------------------------------|-------------|------------------------|
| Fat | Casein | Lactalbumen | Lactose | Dextrin | Maltose | Ca as | P. as | Fe. parts | Vitamin D per fl. oz. |
| 3.1% | 1% | 0.7% | 7.3% | | 3.3% | CaO | P ₂ O ₅ | per million | not less than 14 units |
| | | | | | | 0.09% | 0.16% | 4 | |

This food is intended for use from birth to 3 months, or for longer periods in dyspeptic infants, who tolerate it readily.

ALLENBURYS Humanised MILK FOOD No. 2 (Entirely Free from Starch)

Milk Food No. 2 is prepared in exactly the same way as No. 1 and retains its general features. It is intended for use during the second trimester when digestion is established, and it contains a higher proportion of milk protein and correspondingly less carbohydrate. The mineral content is adequate in respect of calcium, phosphorus and iron, and each fluid ounce of reconstituted food contains not less than 14 international units of vitamin D.

ALLENBURYS MALTED FOOD No. 3 (The First Step to Weaning)

This food introduces partially converted starch at the seventh month. It has a mineral and vitamin content equal to No. 1 and No. 2, and it is intended for use in conjunction with the broader dietary now recommended for the second six months of infancy.

| Malted Food No. 3, prepared for use with cows' milk and water has this composition: | | | | | | |
|---|------|--------------|-------|-------------------------------|-------------|------------------------|
| Protein | Fat | Carbohydrate | Ca as | P. as | Fe parts | Vitamin D per fl. oz. |
| 2.8% | 2.2% | 9.7% | CaO | P ₂ O ₅ | per million | not less than 14 units |
| | | | 0.14% | 0.13% | 4 | |

Intestinal Disorders consequent upon Bronchial Infection

Partly owing to the considerable amount of sputum inevitably swallowed by the patient in bronchial affections (especially in children) disorders of the digestive organs may be produced.

A suitable diet and a free daily evacuation tend to prevent these disorders.

Andrews Liver Salt by its effervescence freshens the mouth (often so dry in bronchitis) and by its antacid reaction counteracts gastric catarrh. By producing an easy evacuation, safe even in the presence of myocardial degeneration, it removes the organisms introduced by the swallowed sputum.

★ *N.B.—A large size tin will be sent free on request to any member of the medical profession.*

NEO-FEMERGIN

A NEW UTERINE HAEMOSTATIC WITH AN IMMEDIATE AND PERSISTENT EFFECT.

Each tablet, each c.c. of oral solution, and each ampoule of 1 c.c. contains:

0.00025 Gm.
Ergotamine Tartrate

Ergotamine (from aqueous acetone)

0.000125 Gm.
Ergobasine (ergometrine) tartrate

Ergobasine (from acetone)

"The action of ergot on the uterus is not to be ascribed to any one alkaloid. For obstetric and gynaecological purposes the most suitable drug is one which combines both groups of alkaloids. Unfortunately, very few preparations satisfy this requirement. In the raw material, the alkaloids exhibit extreme variations in form and amount and the alkaloidal content may be reduced as a result of decomposition. Consequently in obstetrics when a rapid as well as a reliable action is required, the crude drug is unsuitable. In employing it, the obstetrician employs an unreliable medicament. In order to ensure certainty of action and accurate dosage, the use of pure active principles is inevitable."

"Combined treatment with ergotamine and ergobasine is to be recommended. Thus, a rapidly acting constituent is combined with one the action of which is long sustained. Side effects are reduced."

Helv. med. Acta, 4, 13, 1937.

ORGANOTHERAPY*

BY

SIR WALTER LANGDON-BROWN, M.D., D.Sc., F.R.C.P.

Emeritus Professor of Physic in the University of Cambridge; Consulting Physician to St. Bartholomew's Hospital, etc.

At the outset I must insist that this is a discussion on organotherapy and not on endocrinology in general. I have said before that organotherapy of necessity lags behind endocrinology, which is as it should be; the scientific foundation must be secure before intelligent therapy is possible. Of late, however, therapy has made rapid advances, principally in relation to the sex hormones. This discussion is therefore timely, and should provide a useful antidote to the unscientific exploitation of endocrinology which is rife to-day. Every scientific advance seems doomed to be dogged and shadowed by a new quackery: hypnotism, electricity, light treatment, psychotherapy, and vaccines have each in turn suffered this, and it is too much to expect that biochemistry would escape. I read in a lay paper recently that 90 per cent. of bodily troubles were due to glands, and it was implied that they could be remedied by gland treatment. Organotherapy may well pray to be delivered from such friends!

My remarks will be almost entirely concerned with general principles, for I am to be followed by a number of speakers whose own researches have added to our knowledge and who will speak from their own experience on various topics. It is of interest to me to recall that the whole subject has grown up in my own professional lifetime. For it was in my second year at Cambridge that G. R. Murray first successfully treated a case of myxoedema by thyroid extract. He had been told he might just as well expect to treat tabes with an emulsion of spinal cord, so little had Claude Bernard's conception of internal secretion taken hold of the profession. We must not complain of scepticism, however, considering how much damage credulity has done. But it did seem to me that the late Professor Swale Vincent erred on the side of caution when he maintained that the fact that a juice possessing certain pharmacological properties could be squeezed out of the pituitary body threw no light on the function of the gland. Even as recently as 1921 Sir James Berry announced himself an impenitent sceptic as to the parathyroids having any separate function from the thyroid.

Three Lines of Advance

Starling's conception of a chemical control of the body by hormones which he enunciated in 1905 found powerful support, however, in three subsequent discoveries: first, of vitamins—exogenous hormones, as they have been

called; and, secondly, from the observations of Loewi and of Dale, from which we learned that the secretion of adrenalin and pituitrin by structures of nervous origin are only special instances of a general law—namely, that a chemical substance is liberated at every nerve-ending on stimulation. In Hopkins's illuminating phrase—chemical substances produced locally and temporarily translate for the tissues the messages received through the nerves. The histamine-like substance and the P-substance described by Lewis as playing an important part in manifestations of allergy and of pain constitute another instance of the chemical control of the body. A third line of advance was the discovery by the Needhams and Waddington that Spemann's organizer in the embryo was not cellular but chemical in its activities, and that it was closely related to oestrin. The relation between the stimulants to normal and abnormal growth has been ably demonstrated by J. W. Cook and E. C. Dodds (1934), and we know that from sterols normally occurring in the body a deranged metabolism may produce specific carcinogenetic substances which will stimulate certain cells to wild proliferation. There is indeed considerable overlap between the chemical constitution of certain hormones, vitamins, and carcinogens. Further, the co-operation of organic chemists with the biologists has led to the preparation of synthetic hormones, and it has been found that simpler chemical substances than those existing in Nature may be adequate to produce the biological effect. These basal groups are, in Dodds's happy phrase, skeleton keys which can pick the physiological lock. We are learning, too, that some of them can have other than their normal specific effects—these are, as he says, pass-keys.

Antihormones

Hormones belonging as they do to the innate defences of the body, it was assumed for a good many years that they would not act as antigens. Doubts on the truth of this generalization were first thrown by J. B. Collip's (1934, 1935) observation that parathormone gradually lost its effect on repeated injection. Subsequently the existence of antihormones was established for the gonadotropic growth and ketogenic hormones of the pituitary and suspected for the diabetogenic and adrenotropic hormones. Collip regards a hormone-antihormone linkage as a normal condition, but there is no evidence that these "anti" substances are produced in the endocrine glands (Loeser, 1937). Nevertheless they are not merely precipitin re-

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Plymouth, 1938.

actions, for they have been obtained against protein-free extracts, and although not always specific for the particular animal, they are absolutely specific for the individual hormone. It is of interest to note that while the antibodies for tropic hormones can be transferred from one animal to another, the antibodies for simpler hormones, such as parathormone, thyroxine, adrenalin, and insulin, cannot be so transferred (Bauer and others, 1936, 1937).

Hormones and Mineral Metabolism

A further advance in organotherapy was made when the interaction between hormones and mineral metabolism was realized. This was first recognized in the instance of calcium and phosphorus in relation to parathormone, but, not long after, the importance of sodium and potassium ions in relation to the adrenal cortical hormone was discovered. It is now claimed by Rivoire (1937) that just as generalized osteitis fibrosa is associated with a parathyroid adenoma, so myasthenia gravis is associated with a thymic adenoma, as indeed others have observed, and that just as sodium does good and potassium harm in adrenal cortical deficiency, so potassium is beneficial and sodium harmful in myasthenia gravis. Dr. R. S. Aitken informs me, however, that he has not found potassium salts of much benefit in myasthenia gravis. When we add to this list the well-recognized association between the thyroid and iodine and also between haemopoietin and iron in metabolism, it is clear that there is a field for research on the connexion between hormones and mineral metabolism. While on this topic it may be relevant to mention H. Zondek's (1935a) conception of hormones circulating in the blood in an inactive form, and only being activated on reaching their destination, where their action as physical catalysts is modified by electrolytes. Thus he claims that calcium inhibits and potassium increases the effect of thyroxine on the cell. Such matters, however, remain chiefly of academic interest at present, but I hope I have cleared the way for a consideration of the general principles of organotherapy.

Three Postulates for Rational Organotherapy

We may lay down these postulates for rational organotherapy:

- A. The gland in question forms an internal secretion.
- B. The active principle or principles of this secretion can be extracted.
- C. A method of administration of this extract is available which will admit of its utilization by the body.

If and when these postulates have been fulfilled, organotherapy may be employed in the following ways.

1. *As Substitution Therapy.*—To replace the absent or deficient secretion of a gland that is involved in a destructive lesion, or where there is relative insufficiency owing to overaction of some antagonistic gland. Here the hormone is intended to produce a chronic effect. It is only necessary to instance thyroid extract and insulin as examples, and I select them for this reason. For success it must be possible for intermittent doses to replace satisfactorily the slow and more constant secretion which normally occurs. Thyroid extract does this most satisfactorily, and the recent work on insulin has been directed towards slowing down its effect by combination with protamine and zinc so as to imitate more closely the conditions obtaining in the body. On the subject of the active absorption of hormones and the methods of prolonging their action I may refer you to the paper by Dr. V. S. Parkes (1938). It is important to observe that sub-

stitution therapy does not imply that thereby the body may be induced to form its own hormone; indeed, the evidence is all against any such effect.

2. *As Pharmacological Agents.*—Where their known physiological action may be useful, quite apart from any recognizable defect in the patient's own glands. Here a sudden effect is usually aimed at. The injection of adrenaline for the relief of an asthmatic paroxysm is a well-recognized example of this. The production of insulin shock in the treatment of schizophrenia might be cited as another example, though recent observations (Salm, 1937) on the damage which can be wrought on the nerve cells by this procedure should give us pause.

3. *As an Antagonist to Another Hormone.*—Here we can instance insulin in the treatment of hyperthyroidism, pitressin and adrenaline as antagonists to insulin, also oestrin in the attempt to neutralize an overacting pituitary, which has perhaps been more successful in menopausal disturbances than in other directions, though Kirklin and Wilder (1936) claim success for oestrone in the relief of acromegaly. Zuckerman showed that testosterone suppressed ovulation in monkeys, while Loeser found clinically that it led to atrophy of the endometrium and was of therapeutic value in menorrhagia. Levy Simpson (1938) has also used it with some success as a method of neutralizing the thyrotropic hormone in hyperthyroidism.

4. *To Influence General Metabolism.*—Thyroid may certainly help to quicken up general metabolism if it is desired to do so, even in the absence of hypothyroidism. Insulin, adequately covered by dextrose, is often helpful in anorexia nervosa and other wasting diseases. It is claimed for oestrin that it has a favourable influence on impaired carbohydrate metabolism; indeed, Glen and Eaton (1938) found that dihydroxyoestrin increased sugar tolerance in a severe insulin-resistant case of diabetes. But as this effect is presumably antagonistic to the diabetogenic pituitary hormone it should perhaps be classed under heading No. 3.

5. *As an Attempt to Utilize Antihormonal Activity.*—There are two possible therapeutic applications of antihormones to correct over-activity of endocrine glands: (a) *passive neutralization* by means of the antihormone produced in another animal by injecting it with the corresponding hormone, and (b) *active antagonism* by injecting the patient with sub-threshold doses of the hormone in question and thus causing him to produce his own antihormone. The first method has had some limited success experimentally, and Loeser (1937) found the antithyrotropic hormone effective even when given by the mouth. I am unaware, however, of any clinical successes by this method. The second method, although imitating vaccine therapy, does run the risk of aggravating the disease. Hertz and Hisaw (1934) have succeeded with sub-threshold doses of gonadotropic hormone in rendering an animal's ovaries resistant to subsequent large and usually effective doses.

It must be admitted, however, that antihormonal action has so far proved a hindrance rather than a help to organotherapy, particularly so far as the pituitary tropic hormones are concerned. Thus Spence and Wits (1933) found that patients soon became resistant to the thyrotropic hormone, and were able to demonstrate the presence of the antithyrotropic hormone in their serum. It seems generally advisable also to give the growth hormone periodically with intervals of rest, in order to avoid the development of the antihormone.

6. *Employed Empirically.*—As time goes on we may expect to find instances originally placed in this category

transferred to others. Indeed, this process is actually in progress. Thus while I can offer no rational basis for the relief given by pitressin for the pain of herpes zoster and its frequent neuralgic sequel (W. H. Marshall, in a private communication), the influence of parathormone on intestinal colic may perhaps be explained by the sedative effect of hypercalcaemia on muscular tone. The rationale of the treatment of chronic mastitis by oestrin with or without the addition of prolactin is not yet obvious, since both these hormones increase the activity of the breasts. The relation between oestrin and the condition of the nasal mucosa is, however, of special interest. In animals the olfactory sense is clearly associated with sex, and the observations of Mortimer, Wright, and Collip (1937) on the effect of oestrin in the treatment of atrophic rhinitis are important. This has led A. S. Hoseason (*Journal*, October 1, p. 703) to call attention to the opposite condition of vasomotor rhinitis, and compare it with the condition produced experimentally in monkeys by overdosage with oestrin.

I do not, however, intend to say much about organotherapy by sex hormones, because, this being at the moment the most rapidly advancing branch of endocrinology, some of the subsequent speakers will devote the whole of their contributions to it. I would, nevertheless, point out that the increasing use of oestrogenic substances in the treatment of disorders in the male supports Dodds's conception of the "skeleton key" action of certain hormones.

Deleterious Effects

That self-medication by thyroid extract often leads to disastrous effects is generally recognized. Any really active therapeutic agent is capable of misuse. The danger of repeatedly inducing insulin hypoglycaemia has already been referred to. Parathormone can clearly have a destructive effect upon bone and may induce the formation of renal calculi; fortunately these effects are partially limited by its exciting the production of an antihormone. The administration of oestrin for the vulvovaginitis of children has been followed by precocious puberty, both physically and psychically. Dodds and Noble (1937) have demonstrated the harmful effect of repeated injections of pituitrin on the gastric mucosa. Whether continued injections of adrenaline can produce arteriosclerosis has been much disputed. On the whole it seems unlikely. I saw one striking case under the care of Dr. George Graham where a young woman developed a systolic blood pressure of 280 mm. Hg after frequent injections extending over two years, but in view of the rarity of such a sequence she may have had a coincident malignant hypertension. I think the experimental evidence as to the carcinogenic effect of oestrin need not lead us to fear a clinical counterpart; it has been calculated that it would take fifty years for its ordinary administration to have this effect in human beings.

Routes of Administration

(a) *Oral*.—The early triumphs of thyroid medication by this route led to disappointment when it was found that it was not equally effective for other hormones. There seems to be a good case for the efficacy of this method for certain sex hormones, though about five times as large a dose is required compared with injection. Haemopoietin and ventriculin may fairly be regarded as hormones, and are undoubtedly effective given thus. As to certain properties of anterior pituitary, I must confess that *pace* the pharmacologists I have seen effects follow

its oral administration too frequently to believe they were merely due to coincidence. But here I expect I am in a minority.

(b) *Nasal*.—As the post-pituitary is an upgrowth from the nasal mucosa, it was suggested by Blumgart that this route might be effective for pituitrin, and so it proved to be. It remains true, however, that the

(c) *Subcutaneous* is the only effective route for the majority of hormones, reinforced by

(d) *Intravenous* administration in emergencies such as diabetic coma.

(e) *Rectal* administration is seldom called for, and though advocated for insulin it offers quite as great drawbacks as the hypodermic syringe.

(f) *Cutaneous*.—B. Zondek (1938) has called attention to the fact that the oestrogenic hormone dissolved in benzol, ether, or alcohol is completely absorbed by the skin.

Receptivity of Hormones by the Tissues

Although intensive study has been made of the pharmacology of hormones, there is evidently another aspect which has so far been little investigated. That is the receptivity of the tissues. How this normally varies in accordance with the needs of the body can be succinctly illustrated by the metamorphosing tadpole. Under the influence of thyroxine the cells of the gill-covers atrophy, while at the same time the limb-buds grow actively. This may perhaps be regarded simply as an example of thyroxine speeding up metabolism in the direction in which it is normally going, but other instances cannot be so simply explained.

Some thirty years ago Langley and Elliott independently postulated the existence of a receptive substance between the nerve-ending and the tissue as necessary to explain the facts then known. If such a postulate was required then, how much more is it needed to-day! Just as the appropriate chemical material, such as pilocarpine or atropine, may get into this receptive substance, so may a toxin. G. N. Myers has shown that a therapeutic drug may seize on the receptive substance and thus bar the way to the ingress of the toxin. It seems to me that the pharmacology of the future will have to concern itself with the natural history of these receptive substances, and find out in what manner they can be helped by drugs, both positively, by facilitating their reactions, and negatively, by blocking the way against the entrance of toxins. Nor is this topic remote from my subject, for H. Zondek (1935b) maintains that the absorption of a hormone, such as thyroxine, is decreased in the presence of narcotics such as the barbiturates, which are able to adhere to the cell surface and thus to displace the hormone from it. But it is also germane to my subject in a wider sense. We are still entirely without any conception why a particular cell should be sensitive to a particular chemical substance or why the same substance should augment the activity of one type of cell and inhibit that of another. The nature of these receptive substances is a problem to which many minds are beginning to devote themselves. The importance of the responsive capacity of the receptor tissues was clearly indicated by Harrison in his Harveian Lectures for 1934. He showed that when transplantation is effected between embryos of species of different sizes the transplant responds according to its inherited growth capacity rather than to its new endocrine environment. As Keith pointed out some years ago, the partial gigantisms in certain cases of hyperpituitarism can only be explained

on the theory that the locally hypertrophied tissues had developed a special sensitiveness to the growth hormone. H. M. Evans has shown that the response of the dachshund and of the sheep-dog to injections of the pituitary growth hormone is entirely different. Indeed, if such things were not so, it would be difficult to account for structural plasticity in the hands of the breeder.

It must have fallen to the lot of everyone who has treated cases of pituitary obesity to find some patients entirely refractory to treatment identical with that which has been successful with others. Yet clinically no difference could be detected between the two groups. I know that there are authorities who maintain that obesity can always be reduced by diet alone; I do not know if they would add that the patient can also be kept in good health. I believe that retention of water is one factor in preventing reduction of weight, and I sometimes speculate on the possibility of putting on weight by assimilation of oxygen: how otherwise does the hibernating animal become heavier? But apart from such controversial matters, it seems clear that cases of obesity of admittedly endocrine origin respond so differently that some difference of receptivity is probable.

In concluding this necessarily summary introduction to the discussion may I express the hope that research on the synthetic hormones may effect two things: first, the discovery of simple basal groups which can produce the biological effect and yet escape disintegration by the digestive juices; and, secondly, reduce materially the cost of production. At present the cost of many is prohibitive except for the very rich and for the hospital class.

L. Rizzi (*Riforma med.*, 1938, 54, 1222), who records an illustrative case, states that in most of the cases of pituitary haemorrhages on record there are minute punctate haemorrhages indicating toxic degeneration, or merely sudden increase of pressure, corresponding to the small haemorrhages observed in all the other organs. Large pituitary haemorrhages are very rare, and their origin is obscure. Almost all cases of this kind have shown old haemorrhages, which had given rise to more or less definite pituitary syndromes. The present case was that of a woman, aged 49, the subject of diffuse glomerular nephritis with hypertension, who six days before death developed severe cerebral symptoms due to uraemia. In addition to well-marked arteriosclerosis and renal sclerosis a large haemorrhagic cyst in the hypophysis was found. The cause of death in this case was the compression of the mid-brain or the general endocranial hypertension produced by the haemorrhage.

TREATMENT OF TUBERCULOSIS IN GUINEA-PIGS WITH SULPHANILAMIDE

BY

G. A. H. BUTTLE, M.A., M.R.C.S.

AND

H. J. PARISH, M.D., D.P.H., M.R.C.P.Ed.

(From the Wellcome Physiological Research Laboratories,
Beckenham, Kent)

The experiments described in this paper were carried out in an attempt to repeat the work of Rich and Follis (1938), who obtained considerable inhibition of the development of tuberculous lesions in guinea-pigs infected with a human strain.

Technique

Infection of Guinea-pigs.—Suspensions of actively growing (six-day) cultures from Petragnani's medium were injected subcutaneously into the right leg of guinea-pigs which averaged 400 grammes in weight. Two virulent strains were used, as follows:

Human strain, R. 2: Twenty guinea-pigs received 0.05 mg. of culture and twenty 0.5 mg.

Bovine strain, BV. 28: Twenty guinea-pigs received 0.01 mg. and twenty 0.1 mg.

With the aid of an opacity standard tube we estimated that 1 mg. of culture contained approximately 2,000 million tubercle bacilli.

Treatment with Sulphanilamide.—Half the animals in each group were kept as controls and half were given sulphanilamide (50 per cent. suspension in 5 per cent. gum arabic) four times daily by mouth. A total of 500 mg. (100 mg. at 9 a.m., 1.30 p.m., and 5 p.m., and 200 mg. at 10 p.m.) was given daily for five days; these doses were halved from the sixth to the forty-second day, when all survivors in both treated and control groups were killed. Unlike Rich and Follis, who deposited the drug in the cheek pouch, we induced the swallowing reflex by ejecting the suspension from a syringe on to the back of the tongue and pharynx. Almost all the material thus administered was retained.

Toxic Effects of Sulphanilamide

The treatment we employed for the first five days of the experiment—namely, 500 mg. daily—was regarded as the optimum therapeutic dosage by Rich and Follis, who noted evidence of overdosage, however, in certain guinea-pigs which had been treated for three to six weeks. We reduced the dosage to 250 mg. after the fifth day, because some guinea-pigs undergoing treatment soon became ill with characteristic toxic signs—loss of weight and temporary paralysis.

The average weights of the treated and control groups of guinea-pigs were approximately the same (400 grammes) at the beginning of the experiment, but the treated animals lost an average of 50 grammes during the first week of treatment, whereas the weights of the untreated controls remained stationary. When dosage was reduced towards the end of the first week the general condition of the treated animals improved, although they remained lighter than the untreated controls. Unfortunately, in this preliminary experiment we did not continue to weigh the animals at weekly intervals.

Therapeutic Results

Sulphanilamide did not completely arrest the development of generalized tuberculosis. The lesions of the treated animals that died during the fourth or fifth week of the experiment appeared to be less than those of controls. All the survivors were killed on the forty-second day, when the differences between the groups were as follows:

HUMAN STRAIN, R. 2

The spleens of the control animals were very friable, but those of the treated animals were of almost normal texture. Although macroscopic tuberculous foci were present in the spleens of all the guinea-pigs, they were fewer, much smaller, and showed less tendency to coalesce in the treated group. Spleens from nine controls and nine treated animals were sectioned by Dr. C. L. Oakley, who reported that "tubercles were present in all, but were consistently smaller and showed less tendency to coalesce in the treated animals than in the controls. In many spleens from control animals no normal splenic tissue could be found; in most of the treated animals each tubercle was surrounded by a broad zone of more or less normal spleen. In no instance was there the slightest sign of healing."

In the third series of experiments of Rich and Follis no animals in the fifth week and only one of six animals in the sixth week in the treated group showed macroscopic lesions in the spleen, although all except one showed scattered microscopic tubercles. This is a better result than we were able to obtain in our preliminary experiment.

The spleens of our treated animals (average area of anterior surfaces, 460 sq. mm.) were less enlarged than those of the untreated controls (average, 822 sq. mm.), but this difference was probably partly due to the fall in weight of those treated. Our colleague, Dr. J. W. Trevan, kindly examined the data statistically, and concluded that the size of the spleen did not provide any important evidence as to the intensity of infection.

Many tuberculous foci were present in the lungs of both our treated and untreated animals, but they were somewhat fewer and more discrete in the former group, and had less associated basal consolidation. The inguinal and tracheo-bronchial lymphatic glands were much smaller and not so caseous in treated guinea-pigs.

The livers of many animals showed macroscopic lesions, and the variation in the extent of the infection in the treated and control groups was slight. There were no significant differences in the amounts of pus in the local lesions at the site of inoculation.

BOVINE STRAIN, BV. 28

Treatment had possibly a slight inhibitory effect in guinea-pigs—less than was obtained in the experiment with the less virulent human strain, R. 2.

A companion experiment in rabbits showed no evidence of inhibition of tuberculosis with treatment. Eight control and eight treated animals were used, 3,750 mg. of the drug being administered daily to each treated rabbit in divided dosage.

Summary and Conclusions

Sulphanilamide appears to produce some degree of inhibition of an infection of guinea-pigs with a human strain of the tubercle bacillus. Our results are less striking than those of Rich and Follis—possibly due to a difference in strain.

The drug had very little influence on the course of infection in guinea-pigs and none in rabbits when a bovine strain was used.

We agree with Rich and Follis that it would be regrettable if any premature and unjustifiable conclusions were drawn regarding the treatment of tuberculosis. Further prolonged investigations with sulphanilamide and other

preparations are clearly necessary under carefully controlled conditions, special attention being paid to the toxicity of the drugs employed.

We are indebted to Dr. A. Stanley Griffith for the virulent bovine strain, BV. 28, and to Drs. J. W. Trevan and C. L. Oakley for their valuable help.

THE SARCOIDOSIS OF BOECK

BY

R. BODLEY SCOTT, M.A., D.M., M.R.C.P.

First Assistant, Medical Professorial Unit, St. Bartholomew's Hospital; Assistant Physician, Woolwich War Memorial Hospital

(WITH SPECIAL PLATE)

The individual lesions of sarcoidosis have been recognized for many years, but, as patients would seek the advice of the dermatologist for one, the general physician for another, and the ophthalmologist for a third, the synthesis which showed them all to be expressions of the same morbid process was long delayed. However, the concept of a generalized disease with infiltrations of the skin in only a moiety of the cases is now widely admitted. Jonathan Hutchinson (1875) was the first to recognize the complaint, although priority is usually given to other workers—Besnier (1889), Tenneson (1892), and Boeck (1899). He "was accustomed . . . to designate the condition Mabey's malady"—from the name of his patient—"and although other and more scientific names might be devised, it is perhaps doubtful whether they would be more convenient" (1900). Longcope and Pierson (1937) quote nine other synonyms, and their list is by no means exhaustive. In the present paper the term "sarcoidosis of Boeck" is used, not for its intrinsic merit, which is little, but because it is familiar and bears no causative connotation.

The sarcoidosis of Boeck is a disease of long duration with a tendency to spontaneous remission; it is characterized by enlargement of lymph-nodes and spleen, by infiltrations of the skin, lungs, and bones of the fingers, by enlargement of parotid and lacrimal glands, and by iridocyclitis. One or more of these changes may be present in any individual case. It is my purpose to describe the clinical picture of the disease and to present very briefly eight new cases.

Sarcoidosis is not a rare disease, but it is difficult to give its frequency numerical expression as the patients are scattered through the special departments of a hospital. In over 300 histological examinations of lymph-nodes excised to establish a diagnosis of Hodgkin's disease, sarcoidosis was found once to every eleven cases of lymphadenoma; when to these are added the patients who attend the dermatologist for cutaneous sarcoid and some cases of "tuberculous" iridocyclitis from the ophthalmologist, it will be appreciated that its frequency demands for it a wider recognition. The eight cases reported here were collected in less than a year.

The Clinical Picture

The course of the disease is one of extreme chronicity unaccompanied in the majority by such symptoms of intoxication as pyrexia or emaciation, although there may be complaint of tiredness. The patient commonly comes

under observation on account of enlargement of lymph-nodes, or, if some other manifestation provides the first symptom, lymphadenopathy is found. The initial complaints in the present cases are tabulated below:

| | | | |
|-------------------------|---|----------------------------|---|
| Lymphadenopathy | 2 | Swelling in breast | 1 |
| Cutaneous lesions | 2 | Swelling of parotid and .. | 1 |
| Cough | 1 | lacrimal glands | 1 |
| Tiredness | 2 | Swelling of fingers | 1 |

Gradually other lesions appear while the earlier ones involute, and this process may continue over a number of years, tending often towards complete recovery.

Lymphadenopathy and Splenomegaly

Enlargement of superficial lymph-nodes is present at some stage in all cases; it is usually generalized and of moderate degree, but on occasions it is limited to one group of nodes and is of such an order as to raise the suspicion of Hodgkin's disease. The enlarged nodes are painless and insensitive, discrete and mobile; while the patient is under observation they may retrogress and become impalpable. Splenomegaly is common and may sometimes be considerable. The spleen was palpable in five of the present cases. It is probable that some of the cases reported as tuberculous splenomegaly with miliary tuberculosis of the lungs (Hickling, 1938) are instances of sarcoidosis.

Cutaneous Lesions

The infiltrations of the skin are often so bizarre that they have attracted much attention in the past, and in consequence sarcoidosis was for years regarded as a disease of the skin with occasional visceral manifestations. The frequency of these lesions is difficult to compute, but it is probable that they are found in not more than 50 per cent. of all cases of sarcoidosis; clinically the cutaneous lesions fall into four groups:

1. *Miliary Lupoid* (Boeck, 1899, 1905).—This occurs in two forms: first as an eruption of small red-brown papules affecting the cheeks, forehead, extensor surfaces of the arms, the buttocks, and the back of the legs. The papules are usually smooth, but may show hyperkeratosis. This fine form of miliary lupoid occasionally occurs in plaques resembling lichen planus (lichenoid variety). The second form is the nodular sarcoid where lesions occur most frequently on the face and limbs. The nodules during the stage of eruption may reach a diameter of 5 cm.; they are smooth, slightly elevated, and red-blue in colour; in the florid stage, which may last twenty years, they increase in volume, become violaceous, and the surface, which never ulcerates, is often telangiectatic. The whole process is one of extreme torpidity. In the stage of involution, central flattening gives rise to an annular appearance, and telangiectasis and pigmentation of the margins are common.

2. *Lupus Pernio* (Bcsnier, 1889; Tenneson, 1892).—This is a diffuse infiltrative lesion affecting the nose, cheeks, and sometimes the lobes of the ears. The eruption has a sharp border with a surface which may appear almost burnished. Perniotic lesions of the fingers with associated bone changes are common.

3. *Angio-Lupoid* (Brocq and Pautrier, 1913).—This lesion is less common. It occurs in women of middle age, and consists of soft infiltrated plaques on the sides of the root of the nose, violet-red in colour with marked telangiectasis.

Erythrodermie Sarcoidique (Schaumann, 1924) appears as large superficial serpiginous red areas on the front of the legs and thighs.

An isolated lesion of the skin, especially of the types described as miliary lupoid and angio-lupoid, is not always sufficient for a diagnosis of sarcoidosis, as cutaneous infiltrations which are macroscopically and microscopically identical may be due to other causes. These causes are leprosy (tuberculoid type; Motta, 1931), leishmaniasis ("bouton d'orient"; Dupont, 1930), and possibly tuberculosis and syphilis. Of the cases reported here four had skin eruptions at one time or another. Case I showed the coarse nodular sarcoid, Cases III and VII the fine miliary lupoid, and Case VIII was an example of lupus pernio.

Pulmonary Lesions

The intrathoracic changes are of two types; first and most common is the enlargement of mediastinal or hilar lymph-nodes, which may be sufficient to simulate Hodgkin's disease, although in sarcoidosis the hilar lymphadenopathy predominates, while in lymphadenoma the form is more commonly mediastinal. The second type of lesion is seen radiographically as a diffuse mottling throughout the lung fields, simulating that of miliary tuberculosis but usually coarser and less regularly disposed. There is evidence to show that this miliary lesion may result in pulmonary fibrosis and even produce heart failure. Five of the present cases showed hilar or mediastinal lymphadenopathy, and one the miliary change. It is remarkable that these extensive radiographic abnormalities are accompanied by so few symptoms and physical signs; cough was a feature of two cases, but there were no sputa, and the physical signs were limited to basal crepitation. It seems possible, as Bödecker (1932) has suggested, that some of the cases reported as chronic miliary pulmonary tuberculosis may be examples of this disease. (Plate, Figs. 1, 2, and 3.)

Bones

The changes occur almost exclusively in the phalanges of the hands and feet. Clinically they make their appearance as painful fusiform swellings of the fingers. The radiographic changes were fully described by Jüngling (1920) as osteitis multiplex cystica vel cystoides tuberculosa, although they had been recognized eighteen years previously by Kienbock (1902) and their association with lupus pernio noted by Kreibech (1904). The normal structure of the phalanx is replaced by a lace-like network with small areas of rarefaction often surrounded by a zone of increased density. On occasion these radiographic changes are unaccompanied by clinical evidence of disease, but the process may advance to cause mutilation or may heal so completely that the finger appears normal except for some deformity of the nail. Osteitis multiplex occurred in two of the present series (Fig. 4).

Other Lesions

Enlargement of the parotid and lacrimal glands has often been noted; in this series the parotid glands were enlarged in one, and the lacrimal glands in one, and both parotid and lacrimal glands in a third case. This patient presented the clinical picture of Mikulicz's syndrome. Three of Longepé and Pierson's cases showed affection of one or other of these glands.

Iridocyclitis is stated to occur in about 10 per cent. of cases of sarcoidosis (Blegvad, 1931); it is of the type described as "tuberculous" or "paratuberculous." This affection is often resistant to treatment, and may lead to blindness, as in one of the two cases affected in this series. Other ocular lesions are uncommon, but Blegvad (1931) has reported infiltration of the conjunctiva.

Several writers have suggested that the uveo-parotid syndrome of Heerfordt (1909) is inseparable from sarcoidosis; the histological changes are identical, and a perusal of case reports shows that all gradations, from iridocyclitis with swelling of the parotid glands to the well-known clinical picture of miliary lupoid, occur. Pautrier (1938) and Slot, Goedbloed, and Goslings (1938) have reported cases which show clearly that uveo-parotitis must be regarded as a clinical variant of sarcoidosis.

Infiltrations in many other sites have been recorded, but those already described occur often enough to constitute an easily recognizable picture. Boeck (1916) and Mylius (1928) have stressed the frequency of lesions in the mucosae of the upper air passages; the breast was involved in one of the present cases and in one seen by Goeckermann (1928). There are records of lesions in the testicle (Pautrier, 1935), the hypophysis (Schaumann, 1936), and the optic nerve (Reis and Rothfeld, 1931).

Treatment

It is difficult to evaluate the results of treatment in a disease which so often shows spontaneous involution. Radiotherapy, gold, arsenic, and tuberculin are generally held to be useless, although improvement followed the first two in some of the present cases. Lomholt (1937) has reported benefit from antileprol.

Pathology

The observation that a negative Mantoux reaction is common in sarcoidosis has given rise to much speculation. It has been urged that it is an instance of cutaneous "anergy" (Martenstein, 1924), but it has never been established that the reaction is negative more frequently than in a series of normal controls, and Kissmeyer (1932) concludes that the percentage of negative reactions is what would be expected in non-tuberculous subjects of the same age. The proportion of negative tests in different series varies considerably.

Anaemia is mild or absent, and examination of the blood often reveals a moderate mononucleosis; two of the present cases showed an eosinophilia such as was noted by Longcope and Pierson (1937). An increase in the plasma globulin has been observed by Salvesen (1935), and was present in one of my patients.

The histological changes are identical in all the affected tissues. There is a proliferation of histiocytes to form discrete collections of epithelioid cells, among which an occasional giant cell may be seen. Surrounding lymphocytic infiltration is lacking; there is no caseation, and tubercle bacilli cannot be demonstrated. The lesions may be said to consist of "pathological tubercles," and the changes are familiar to all morbid anatomists under the name of hyperplastic or endothelial "tuberculosis," although a more accurate descriptive term would be histiocytic sinus reticulosis (Fig. 5).

Aetiology

An acrimonious dispute over the nature of sarcoidosis has been in progress for many years. Three hypotheses have been adduced: first, that it is due to tuberculosis; secondly, that it is a non-specific tissue response which may be evoked by a variety of pathogenic agents such as the tubercle and lepra bacilli, the *Spirochaeta pallida*, and leishmania; and, thirdly, that it is a systematized disease of lympho-reticular (reticulo-endothelial) tissue comparable to Hodgkin's disease and similarly of unknown aetiology. The first hypothesis has been favoured

by dermatological opinion; but inoculation experiments, with a few doubtful exceptions, have been consistently negative, and acid-fast bacilli have been demonstrated only in a handful of cases, all of which Kissmeyer (1932) has shown to be open to criticism. The only facts favouring a tuberculous aetiology are the microscopical appearances, and the observations of Schaumann (1923) and others that some patients have died of phthisis. Most pathologists will admit that the histological signature of the tubercle bacillus is susceptible of forgery, and phthisis may clearly be a secondary infection in an occasional case; indeed, it is possible that the pulmonary fibrosis which sometimes occurs may be a predisposing factor. The second hypothesis also has its origin in dermatological writings, and, although it must be admitted that similar cutaneous lesions may be due to Hansen's bacillus (tuberculoïd leprosy) or leishmaniasis (Dupont, 1930), it is unbelievable that the whole characteristic and well-defined syndrome of sarcoidosis could be anything but a specific disease due to one cause. The suggestion that sarcoidosis falls into the same category as leucosis and Hodgkin's disease and must rank as a reticulosis (Pullinger, 1932; Ross, 1933; Bodley Scott and Robb-Smith, 1936) is finding increasing favour, although its cause remains as obscure as that of the other diseases of this group.

Case Reports

CASE I

A married woman, this patient came of healthy stock, and had had no illness, except catarrhal jaundice in childhood, until the age of 34 years, when she noticed an eruption above the right eyebrow. Ten months later similar spots appeared on the arms, knees, and neck; she began to tire easily and sweat at night, but there was no loss of weight. On admission to hospital at the age of 35 she was apyrexial and weighed 45 kg. The cutaneous lesions consisted of slightly raised infiltrated areas, oval or circular in shape, and in colour varying from violaceous to yellow-red. All the superficial lymph-nodes were enlarged and of an average diameter of 1 cm. The spleen extended 5 cm. below the left costal margin. A blood count showed a hypochromic anaemia with 58 per cent. haemoglobin and a normal differential count. A skiagram of the chest showed some enlargement of mediastinal nodes, and although the hands appeared normal the radiographic lesions of osteitis multiplex were found in the left middle finger. The Wassermann and Mantoux tests (0.1 mg. O.T.) were negative, and biopsy of a cutaneous nodule showed the histological changes of sarcoidosis. She was treated with ultra-violet light and discharged.

Six months later she was readmitted. The eruption was unchanged, her weight was steady, and lymphadenopathy persisted only in the posterior cervical triangles. The spleen and liver were palpable; the anaemia had been remedied and the differential leucocyte count remained normal. She was discharged after a fortnight, and two and a half years later her condition was the same although her general health remained unimpaired.

At the age of 39 an attack of iridocyclitis, from which she made a complete recovery, was treated at an ophthalmic hospital. During the next six years she improved considerably with injections of sodium morrhuate, but developed a morning cough with sputum. In her forty-fourth, forty-fifth, and forty-sixth winters she had attacks of "pneumonia." At the age of 48 she was still troubled with morning cough and dyspnoea on exertion. Her weight was 45 kg. The eruption had disappeared from the face, but persisted on the arms and back in the form of erythematous areas without infiltration but with an occasional yellow-brown nodule. Shotty lymph-nodes were palpable in the neck, axillae, and groins, and the spleen extended 12 cm. below the costal margin. Crepitation was audible at the base of both lungs. The hands and feet were clinically and radiographically normal, but skiagrams of the chest showed a diffuse fibrosis of both lungs (Fig. 3).

CASE II

In this case, that of a West Indian male native, who was first seen at the age of 18 years on account of palpitations, no cardiovascular disease could be found, but there was enlargement of lymph-nodes in the neck and epitrochlear regions, and the spleen was easily palpable. His weight was 60 kg. The patient's health remained good until the age of 19½ years, when for a few weeks he noted dyspnoea on exertion; his spleen was again found to be enlarged. He was free from symptoms until the age of 28, when he developed a feverish cold, followed a week later by painful swelling of both lacrimal glands. The swellings subsided after a few days and a dry paroxysmal cough appeared. Three months later he began to tire easily; his temperature rose occasionally to 99.5° F. and there was some dyspnoea. He had recurrent sore throat, and his left antrum was thought to be infected, but puncture led to no improvement.

He was admitted to hospital, then being 29 years old. His weight was 79 kg.; he was afebrile, and his pulse frequency varied from 90 to 110 per minute. There were enlarged lymph-nodes in the upper deep cervical groups and in both groins; they were discrete, firm, mobile, and of an average diameter of 1.5 cm. A few crepitations were heard at the base of both lungs. A skiagram of the chest showed great enlargement of the hilar nodes, particularly on the right. The sputum contained no tubercle bacilli. Blood count: erythrocytes, 5,240,000 per c.mm.; haemoglobin, 90 per cent.; colour index, 0.86; leucocytes, 7,700 per c.mm.; neutrophils, 60 per cent.; eosinophils, 9 per cent.; lymphocytes, 7 per cent.; plasma cells, 1 per cent.; monocytes, 14 per cent. Biopsy of a node revealed the changes of sarcoidosis, and the Wassermann reaction was negative.

He was discharged to a sanatorium; and there was a slow improvement in his condition in the next two years.

CASE III

This patient, a married woman with three healthy children, came from a healthy family and had always been well herself, although for as long as she could remember there had been "enlarged glands" in the left side of the neck. When 38 years old she noticed a painless swelling in the right breast, for which she sought admission to hospital. There were small discrete lymph-nodes palpable in the left side of the neck, and in the right breast was a hard mobile well-defined swelling measuring 5 cm. by 4 cm. On excision this was found to have the histological structure of sarcoid tissue, and a lymph-node showed similar changes. At this time she began to be troubled by pain in the left eye, and a year later the right one became similarly affected. At the age of 40½ she was readmitted: enlarged nodes were still present in the left side of the neck, and there was a swelling in the left parotid gland and paresis of the left facial nerve. The eyes showed bilateral iridocyclitis with secondary cataracts, and only perception of light was present. Lymph-nodes removed from the left side of the neck showed sarcoidosis. A radiograph of the chest was normal. Left iridectomy was performed with some improvement, and a year later a similar operation was carried out on the right eye.

At the age of 42 she was blind, apart from perception of light in the left eye; enlarged nodes were palpable on both sides of the neck, and she showed the classical features of myxedema. On the abdominal wall was one small patch of milium lupoid. The blood picture was normal and skiagrams of the chest showed a fine diffuse fibrosis; no radiographic changes were found in the hands. With thyroid therapy her general health improved, and apart from her blindness she began to feel well.

CASE IV

This patient came of a healthy long-lived family, although father, who died after an operation for urethral stricture, was said to have contracted syphilis before marriage. In infancy he had had scarlet fever, mumps, and chicken-pox, but was in good health until the age of 13½ years, when he

began to feel tired at the end of the day. At this time both eyelids and both parotid glands became swollen, there was some pyrexia, and he lost weight. After three months he was admitted to a sanatorium, where he improved and gained weight: the report stated that "no signs of tuberculosis were found." Two months later he was transferred to St. Bartholomew's Hospital; he had been in bed for the previous six weeks, but felt well and was gaining weight; there was no cough. His weight was 43 kg.; he was afebrile, but had a tachycardia of about 100 per minute. Both parotid and both lacrimal glands were enlarged, and there was oedema of the upper lids. The tonsils were fleshy, and shotty lymph-nodes were palpable in both upper deep cervical and inguinal groups. The liver extended 4 cm. below the costal margin, and the tip of the spleen was palpable. A skiagram of the chest showed massive enlargement of hilar and mediastinal nodes. Blood count: erythrocytes, 4,970,000 per c.mm.; haemoglobin, 78 per cent.; colour index, 0.8; leucocytes, 9,600 per c.mm.; neutrophils 58 per cent.; eosinophils, 5 per cent.; lymphocytes, 29 per cent.; monocytes, 7 per cent. Mantoux test (1 mg. O.T.), weak positive. The Wassermann reaction was negative. He was discharged from hospital and spent the subsequent year in Switzerland.

The patient continued to gain weight and to feel well. He was readmitted when 17 years old, and a node which showed the changes of sarcoidosis was removed from the groin (Fig. 5). At that time only the inguinal nodes were palpable; other physical findings were negative, but a skiagram of the chest showed little change from that of two and a half years previously.

CASE V

The patient came of healthy stock and had always been well, except for scarlet fever and mumps in childhood. At the age of 21 she married and subsequently had three pregnancies, all of which terminated in abortion. When 23½ years old red lumps appeared on the skin, following an attack of rheumatism; these faded after a fortnight. Six months later she developed a cough with yellow sputum; there was no sweating and no haemoptysis, but she lost 2 kg. in weight in a month. After six weeks she was admitted to hospital: her weight was then 47 kg.; her temperature occasionally reached 99° F. at night, but there was no tachycardia. Enlarged lymph-nodes were palpable in both sides of the neck and in both groins; none exceeded 1 cm. in diameter. There was flattening and reduced movement over the upper part of the right lung. Examination of the blood showed a haemoglobin of 75 per cent. and a lymphocytosis of 47 per cent. of 7,600 leucocytes per c.mm. The sputum contained no tubercle bacilli; the Mantoux test (0.1 mg. O.T.) and the Wassermann reaction were negative. A skiagram of the chest showed a shadow extending from the mediastinum into the right lung field, with a diffuse mottling of the right upper zone (Fig. 1); there was no radiographic abnormality of the hands. An excised node was histologically typical of sarcoidosis. The patient contracted measles while in the ward and was transferred to a fever hospital. On her return after four weeks the nodes in her neck had decreased in size, but those in the epitrochlear regions were palpable, as were some in the right costo-coracoid group. The tip of the spleen could be felt. Treatment with intravenous crisalbine was instituted, and she was discharged improved after a month. She received continued treatment as an out-patient, and a year later her weight had risen to 57 kg., her general health was excellent, a few small nodes were still palpable, and the mediastinal mass had almost vanished.

CASE VI

A married woman aged 21, who had always been healthy and came of sound stock, this patient had an eruption of painful red swellings on both legs which disappeared after a fortnight. About the same time she noticed a swelling in the right side of the neck; she began to lose strength, was listless, and sweated at night. Her condition remained unchanged until six months later, when swellings appeared under the chin and in the left side of the neck. The

increased steadily in size. She had no cough, but had lost weight. At the age of 22 she was admitted to hospital; she weighed 62 kg. and was aphyrexial. All superficial lymph-nodes were enlarged; the tip of the spleen was palpable and occasional rhonchi were audible in the chest. She had a moderate anaemia with 78 per cent. haemoglobin, but the blood count was otherwise normal. The Mantoux test (0.1 mg. O.T.) and the Wassermann reaction were negative. A skiagram of the chest showed mediastinal glandular enlargement. An excised cervical node had the microscopical appearance of sarcoidosis. After radiotherapy she was discharged from hospital; the nodes were then considerably smaller, but she had lost 4 kg. in weight.

Six months later there was further diminution in the size of the lymph-nodes, and after another three months only those in the axillae remained palpable. At this time a skiagram of the hands showed no bony lesion, but in the lungs a military type of infiltration (Fig. 2) had been added to the mediastinal lymphadenopathy. Her general health was good; she had regained 3 kg., but still complained of some tiredness at the end of the day. A year after her discharge from hospital her weight was 66 kg., she was free from symptoms, no superficial nodes were palpable, and the radiographic appearance of the lungs was normal.

CASE VII

This girl was one of a healthy family and had always been well herself, apart from childish ailments, until the age of 14½ years, when she noticed a small pimple on the right cheek. Six months later a painless swelling appeared in the right side of the neck, increasing slowly in size. At 16 years of age a similar lesion appeared on the left arm; a diagnosis of lupus vulgaris was made, and she was treated with injections and ultra-violet light. She lost no weight, had no fever and no sweats, and her general health was unimpaired. A year later she was admitted to hospital; she was aphyrexial and without tachycardia, and her weight was 46.5 kg. Small patches of typical military lupoid were present on the cheeks, arms, and back. There were enlarged lymph-nodes in both sides of the neck, the greatest measuring 2 cm. by 3 cm.; small nodes were palpable in both axillae and groins. The blood picture was normal; the Mantoux test (0.1 mg. O.T.) and the Wassermann reaction were negative. She was discharged after a stay of eleven days. Eight months later she was readmitted; her weight had increased by 4 kg., but her condition was otherwise unchanged. Skiagrams of the chest and hands were normal, and after a course of radiotherapy the lymph-nodes became smaller.

CASE VIII

A missionary worker whose father died of pulmonary tuberculosis, this patient had herself been healthy, apart from acute appendicitis, until the age of 28, when she had sudden pain and swelling in the fourth left digit. The swelling gradually involved the whole finger, and later the left thumb and index were affected. After a few months the hand became almost normal again. At the age of 42 a red eruption appeared on the right side of the face and slowly spread over the nose and left side of the face. Six years later there was swelling of the lymph-nodes in the left side of the neck which subsided after six months.

She was admitted to hospital when 55 years old. There was some dyspnoea on exertion, but no cough, no loss of weight, and no fever. A typical eruption of lupus pernio affected both cheeks and the nose; shotty lymph-nodes were palpable in both posterior triangles, and a persistent rale was audible at the base of both lungs. There was a fusiform swelling of the proximal phalanx of the left fourth digit, and the terminal phalanx was hyperextended. The blood picture was normal; the Mantoux test (0.1 mg. O.T.) and the Wassermann reaction were negative. Serum proteins: albumin 5.2 grammes and globulin 5.2 grammes per 100 ml. Skiagrams of the chest revealed some fibrosis involving particularly the right lower lobe, and the hands showed the radiographic changes of osteitis multiplex in the first and fourth left digits (Fig. 4).

She was treated with solganol-B-oleosum intramuscularly, and after seven months her health remained good, while the local lesions were unchanged.

Conclusions

1. Sarcoidosis is a systematized disease of lymphoreticular (reticulo-endothelial) tissue in which changes are found particularly in the lymph-nodes, spleen, skin, bones of the hands, lungs, eyes, and salivary glands.
2. The uveo-parotid syndrome of Heerfordt is a clinical variant of sarcoidosis.
3. Its course is prolonged and benign, and it has a tendency towards spontaneous recovery.
4. There is no convincing evidence that sarcoidosis is a manifestation of tuberculosis.
5. It is of common enough occurrence to be a disease of interest to all general physicians.
6. Eight new cases of sarcoidosis are reported.

I am indebted to the physicians of St. Bartholomew's Hospital for permission to make use of their cases, and to Professor Ronald Christie for much helpful and constructive criticism. This work was done during the tenure of a grant from the British Empire Cancer Campaign.

E. H. J. Warns (*Nederl. Tijds. Geneesk.*, 1938, 82, 4426) treated twenty-six patients with osteo-articular tuberculosis by large doses of vitamin C for four and a half months, but without any therapeutic effect except possibly a slight improvement in the general condition. On the other hand, the frequently reported deficiency of vitamin C in tuberculosis was confirmed: its daily consumption by the patients was three to five times the normal. There also appeared to be a certain relation between the daily consumption of vitamin C and the activity of the tuberculous process.

FURTHER EXPERIENCES WITH TOMOGRAPHY IN PULMONARY TUBERCULOSIS

BY

J. B. McDougall, M.D., F.R.C.P.Ed., F.R.S.Ed.

Medical Director, Preston Hall Sanatorium, Aylesford, Kent

AND

J. H. Crawford, M.D.

Assistant Medical Director, Preston Hall

(WITH SPECIAL PLATE)

The theory of tomography, and the principles governing this method of taking x-ray pictures of a section of an organ, have been described in several papers (McDougall, 1936, 1937; McDougall and Crawford, 1937), and the present position has been well summarized in a leading article in the *British Medical Journal* (1937). The value of tomography in cases of pulmonary disease is now fully recognized, and with the elaboration and perfection of relatively simple apparatus this method of investigation is likely to enjoy an increasing popularity.

Technique of Tomography

We have continued to use the Sanitas machine as devised by Grossmann (1935), and since March, 1936, when we first began to use tomography at Preston Hall, nearly 400 patients have been investigated by this method. Grossmann's tomograph has been criticized as expensive, but the quality of the pictures is excellent, and post-mortem confirmation of the appearances of the lesion at different sections has been obtained; these afford complete proof of the general accuracy of the apparatus. Furthermore, the resultant films seem to us to present a greater degree of contrast, a more complete obliteration of unwanted shadows, and a more sharply outlined general detail than are usually obtained with simpler apparatus. Nevertheless, we agree that elaborate and costly apparatus is not essential for tomography, and Twining (1937) and Colyer (1937), working independently in this country, and Ziedses des Plantes (1932) in Holland, have all shown that simple attachments to an ordinary x-ray machine can successfully fulfil the requirements necessary for the production of tomograms.

In Grossmann's tomograph the tube and the Potter-Bucky film holder are attached to opposite ends of a pendulum, and in taking a photograph the tube describes an arc, the extent of which can be controlled. The axis in which the pendulum swings can be brought opposite any desired plane in the patient's body, and it is only objects on this particular plane which are sharply defined on the film. The geometrical principles have already been fully outlined in the papers referred to above; further details need not be discussed here.

Twining realized that an ordinary Potter-Bucky couch, embodying as it does two convenient mechanisms—namely, (1) a column capable of moving parallel to the couch, and (2) a Potter-Bucky film carrier moving along the long axis of the couch—was easily adaptable for tomography. By connecting the tube carrier and film carrier by a suitable lever he obtained the movement required—namely, proportional and opposite movement of the film. In this method, as with Grossmann's tomograph, the patient lies in the recumbent position, but in Colyer's adaptation the tube and film carrier move in a vertical instead of a horizontal plane, and thus the patient

can be photographed in the upright position. It is claimed that with this technique the upper limit of a pleural effusion or the line of a fluid level in a cavity is not obliterated.

Clinically, the widest application of tomography has been in the field of obscure pulmonary lesions, but whilst our own work has been almost entirely limited to cases of pulmonary tuberculosis, valuable information can be obtained by the use of this method in many other regions of the body. Twining has found it of considerable value in certain bone work—for example, the radiology of thin cancellous bones which are obscured by denser structures: the patella, sternum, and sternoclavicular joint, temporo-mandibular joint, zygoma, and cribriform plate, the atlas and axis. In addition the larynx, the pharynx, and the nasal cavity can all be investigated by tomography, and more precise information be obtained than by ordinary radiography.

Descriptive Cases

The cases to be described are offered as a further example of the value of the tomograph in the elucidation and localization of cavities, and the more precise analysis and interpretation of complicated fibrotic disease. A full discussion on the clinical value of tomography has already appeared in the *Proceedings of the Royal Society of Medicine* (1938), and readers are referred to this for further details.

CASE I

A patient aged 48, with a four-years history of pulmonary tuberculosis. Fig. 1A is the ordinary radiograph of the chest; the lesion is seen to be fibrotic in type and bilateral in distribution. The right lung appears to contain old-standing fibro-cavernous disease of the upper zone, with an area of recent infiltration in the lower zone; the dome of the diaphragm on this side is peaked and adherent, and the costo-phrenic angle is obliterated. The left lung shows chronic infiltration over the upper two-thirds, while the lower zone is emphysematous, the diaphragm here being sharply outlined.

Fig. 1B is a tomogram taken at a level of only 5 cm. from the back of the chest. On the right side two air loculi are now apparent over the upper and middle zones, being separated by a band of fibrous tissue at approximately the level of the interlobar fissure. Close to the mediastinum, in the inner part of the upper lobe, is a well-defined cavity, and in the lower lobe diffuse infiltrative disease is present. The left lung shows generalized fibrotic disease with a well-defined cavity in the mid-zone (which was not apparent on the ordinary film).

We feel that in this case the antero-posterior film gave an entirely incomplete picture of the actual pathological features of the lesion, and in view of the fact that the physical signs in this case were most indefinite, the existence of the spontaneous pneumothorax on the right side must have remained unsuspected in the absence of tomography. The presence of the spontaneous pneumothorax was later confirmed by inserting a pneumothorax needle, when a slightly positive pressure reading was obtained. A thoracoscopy was advised to determine the state of the collapsed portion of lung, but unfortunately the patient refused this investigation.

The entire series of tomograms in this case (not shown here for reasons of space), taken at intervals of 2 cm. from the front to the back of the chest, illustrated very beautifully the gradual appearance of the pneumothorax from the level of the plane of the lung root to the level of the paravertebral sulcus, and also indicated the general position of the cavity shown in the left mid-zone on the tomogram. The topography of the lesion was thus determined.

strated in a way that we have never been able to equal by any other method of radiological investigation, including lateral, stereoscopic, and oblique films. In this particular case the main lesion was found to be situated in the deeper portions of the lung tissue: this finding has been borne out so often in other patients investigated by us that it would appear that the majority of tuberculous lesions in the lung begin at the back and extend by advancing into the anterior sections. Hence it may often occur that ventral tomograms fail to reveal any evidence of disease, while the dorsal sections may indicate extensive lesions.

CASE II

This patient, aged 30, was admitted with a two-and-a-half-years history of pulmonary tuberculosis. Fig. 2a is the ordinary radiograph of the chest taken on admission. On the right side the apex is seen to be cramped and fibrotic, with some "hard" infiltration in the infraclavicular zone. Over the lower zone, in the inner half of the lung field, is a ring shadow; just above the diaphragm the appearance is suggestive of bronchiectasis. The diaphragm itself is well raised, but the patient had not had a phrenic operation. On the left side the apex is also cramped, and the upper and middle zones show some increase in the normal striation, but no definite infiltrative disease.

Fig. 2n is the tomogram of this patient taken 5 cm. from the back of the chest; a very large cavity in the right lower lobe is now quite obvious, with small "daughter cavities" at its lower pole.

CASE III

This patient was 18 years old, and had a history of only six months' duration. Fig. 3a, the ordinary radiograph taken in the erect position, reveals a very large cavity occupying the whole of the left upper lobe and showing a fluid level; below this is considerable mottling and infiltration. The right lung shows fine mottling over the infraclavicular zone, and suggests a recent exudative spread from the main lesion.

Fig. 3b is a lateral tomogram taken of the left lung in the plane of the mid-clavicular line; the upper lobe cavity is now seen to occupy almost the entire depth of the lung from front to back. A second cavity is also visible below the large one, and appears to be lying in the paravertebral sulcus close to the bodies of the vertebrae. This second cavity was not seen on the ordinary type of lateral film which was taken in this case, no doubt being obscured by the dense shadow of the vertebral column.

CASE IV

A young man aged 20 was admitted with a three-months history of chest symptoms. His general condition was good and his sputum negative. The ordinary radiograph, shown in Fig. 4a, revealed, on the left side, slight infiltration at the apex and more definite infiltration over the mid-zone. The right side, appears a little hazy, but shows no definite lesion. His blood sedimentation rate was normal and his physical signs were scanty and indefinite; in view of these findings surgical treatment was not contemplated, but to be completely certain of the extent and nature of the infiltration on the left side tomographic investigation was carried out.

Fig. 4b is the median tomogram in this case, taken midway between the front and back of the chest; in the mid-zone of the left lung, can be clearly seen a fairly large, well-defined cavity with a good deal of pericavernous infiltration. The right lung is clear.

This cavity was quite obscured on the ordinary film, and a further interesting point in Case IV is that the cavity was revealed in the median section only, and was entirely missed on a preliminary series of films which were taken, thus indicating the great importance of careful "sectioning" in cases with an early lesion.

Because of the tomograph findings, repeated cultural examinations of the sputum were done, and the third specimen cultured on Löwenstein's medium proved to be

positive. Meanwhile an artificial pneumothorax had been attempted on the left side, but the pleura was found to be adherent and the induction failed. A left phrenic crush was subsequently carried out, and after five months (during which time he was also at rest) tomography confirmed that the cavity had closed, leaving only a small fibrotic patch. His sputum is now repeatedly negative to culture and the patient has returned to full work.

Conclusions

In view of the many exhaustive papers that have already been published on the additional information given by tomography in the investigation of pulmonary lesions, we have not gone into the discussions of the cases presented here in any great detail, preferring to allow the films to demonstrate for themselves the greater detail and clarity with which a lesion is revealed. A practical point we would stress is that when a large series of tomograms has been taken on an individual patient the films should be placed together on a sufficient number of viewing screens in order that they may be seen *simultaneously*; in this way the gradual change in the distribution of a lesion is emphatically brought out. The method of successive scrutiny of single tomograms on one viewing screen is quite inadequate for the correct assessment of the series as a whole.

We feel that not the least advantage of tomography is the added impetus it gives one to reconsider old problems in a new light, and to delve into the difficulties of the "pathology of the living," to use the late Lord Moynihan's phrase.

It is true that up to the present we have concentrated mainly on the formation and localization of cavities, and the exact determination of the precise area of lung tissue involved by gross disease. But in these days, with the surgical closure of cavities playing an increasingly important part in the treatment of phthisis, it is essential to adopt a more scientific approach to this particular problem than is possible with ordinary methods of radiology of the chest. With very dense lesions, or lesions of homogeneous densities, stereoscopic films are valueless, and with lesions above the clavicle lateral films often fail to be of assistance. But if cavities are to be closed with a minimum of trauma to the patient and a maximum of efficacy, it is essential to know beyond all doubt the *exact* site and extent of the cavities. From the description of the cases given it is obvious that of all the elements of a tuberculous lesion that comprising a cavity system is revealed most clearly by tomography, and we therefore feel that no apology is needed for stressing the value of this mode of investigation for all patients about to undergo a major thoracic operation.

The London Spectacle Mission, which since 1885 has supplied spectacles to deserving poor persons, is now incorporated with the Royal Surgical Aid Society, which has lately celebrated its jubilee. Nearly 2,000,000 sufferers have been supplied with artificial limbs and other surgical aids through this charitable organization, and now spectacles are added to the many other boons it can bestow.

A COMPARISON OF CLINICAL AND BLOOD PICTURES IN ADULT SCURVY

BY

G. H. JENNINGS, M.D., M.R.C.P.

Physician, Redhill County Hospital, Middlesex County
Council; late First Assistant, Department of
Medicine, British Postgraduate Medical
School

AND

A. J. GLAZE BROOK, M.B., B.S., Surg. Lieut. R.N.

Late House-Physician, Hammersmith Hospital, L.C.C.

(WITH SPECIAL PLATE)

Cases of scurvy such as were described by clinicians in past generations are becoming very rare, and at the same time more and more accurate laboratory methods for diagnosing the malady in a latent or pre-clinical stage are being evolved. So accurately quantitative are some of these tests that there might seem to be little place for the clinician in the diagnosis of scurvy, and a consequent danger that he may miss the condition even in its more flagrant forms. For this reason, and because of the rather unusual and deceptive blood picture in one of our cases, we have ventured to present them in this paper.

Case I

This patient, a man aged 52, had led an active and energetic life, and apart from a period of war service spent in India and Mesopotamia had worked continuously on the railways since the age of 18. He came of healthy stock, with no familial tendencies, was married, but had no children. Twenty years ago he had had malaria, and about seven years ago a severe attack of bronchitis; otherwise he had enjoyed good health. For several years, however, he had noticed a tendency to excessive breathlessness on exertion, but could not date the onset of this symptom.

In August, 1937, he noticed a sudden pain in the right shoulder, which he ascribed to rheumatism. The shoulder was not swollen or discoloured; the pain persisted for about four weeks, and then passed completely away. In November he found on rising one morning that the right knee was swollen. The swelling was followed by pain, which gradually increased in severity over a period of fourteen days and then as gradually passed off. The pain kept him awake at night, but was not increased by movement and did not prevent him from getting about. In December he was admitted to the surgical department at the Postgraduate Medical School for treatment of the condition in the right knee. The knee was found to be grossly swollen, with effusion into the joint and much periarticular bruising and redness. Flexion was possible to a right angle only. It was thought that the condition might be of infective origin, although the Wassermann test, the gonococcal complement-fixation test, and culture of aspirated fluid yielded no positive information. While he was in hospital it was noted that he had anaemia with a colour index below unity and a red count of 3,200,000. Radiographs of the joint showed no recognizable abnormality. With symptomatic measures the swelling and pain in the knee cleared up in three weeks, and he was discharged to the out-patient department for treatment of his anaemia. The anaemia, however, progressed, and by January the red count had fallen to 2,240,000, with a colour index of 1.27. Accordingly he was admitted to the medical department on January 15, 1938, with a provisional diagnosis of pernicious anaemia.

CONDITION ON ADMISSION

The patient was a well-built, cheerful man, with pallor of the mucous membranes and a sallow muddy tinge to the skin; he was not in any pain or distress, and was not

dyspnoeic at rest. Temperature, pulse, and respiration rate were normal. The mucosa of the tongue was smooth at the edges but not atrophic. The jaws were edentulous and the gums healthy, with no tendency to sponginess or bleeding. The heart was normal apart from a slight apical systolic murmur. The blood pressure was 155/80. The lungs showed slight emphysematous changes, and the liver was soft and a trifle enlarged; there were no other findings in chest or abdomen. The central nervous system was normal. The right knee was stiff, full flexion not being possible; and there was infiltration and staining of periarticular tissues as a result of former blood extravasation. Multiple small raised petechiae into the hair follicles were present on the extensor aspects of both legs. The patient stated that these had been noticed for some time, but he did not remember when they first occurred as they had never troubled him.

INVESTIGATIONS

Blood Count (15/1/38).—Red cells, 1,900,000 per c.mm.; haemoglobin, 40 per cent.; colour index, 1.05. White cells, 3,000 per c.mm.; reticulocytes, 3.2 per cent.

Price-Jones Curve.—Definitely megalocytic (see chart).

Marrow Puncture.—Definite hyperplasia, the early red cells being more affected than the white cells. Percentages of total marrow cells: haemocytoblasts, 5.5; primary erythroblasts, 39; normoblasts, 14; megaloblasts, 0.5. These findings were compatible with a diagnosis of pernicious anaemia.

Bleeding Time.—Eight and a half minutes.

Coagulation Time.—1 minute 45 seconds (Dale), 12 minutes (Lee)—that is, high normal.

Blood Bilirubin.—0.5 mg. per 100 c.cm.

Urine.—Some red blood cells and leucocytes.

Gastric Juice.—Absence of free acid after histamine.

Gastroscopy (Dr. R. S. Aitken).—Moderately extensive gastric atrophy with several recent haemorrhages in the mucosa.

Electrocardiogram.—Normal.

COURSE AND TREATMENT

On the whole these findings appeared to justify the diagnosis of pernicious anaemia, and liver therapy was at once instituted, at first with anahacmin (8 c.cm. in all) and later with hepastab (14 c.cm. in all). In spite of the high dosage no response was elicited in the blood picture. On February 3 a 600-c.cm. blood transfusion, given with the idea of stimulating the marrow, had no such effect.

The reticulocyte count, while remaining persistently high, showed no crisis, readings fluctuating between 4 per cent. and 9 per cent. being obtained. The blood sedimentation rate corrected for the anaemia present on February 4 was 64 mm. at the end of one hour, and in view of this high reading, the reticulocyte count, and the absence of response to liver a neoplasm was suspected, a suspicion hardened by the finding of occult blood in the stools at this time. Accordingly, full x-ray investigations of the principal bones, the thorax, and the abdomen were carried out, but no evidence of neoplasm was obtained. Liver was discontinued and large doses of iron were tried. The blood picture showed at first some slight improvement with iron, but soon relapsed again (Table I).

On February 8 a cluc was given to the condition underlying this puzzling blood picture when an effusion of blood occurred into the tissue of the left popliteal space and the lower thigh muscles. By the next day the effusion in the left thigh muscles had increased, forming a deep painful bruise, the swelling reaching half-way up the under surface of the thigh. On February 14 another effusion occurred into the right thigh, forming an extensive haematoma around the external malleolus, and the discoloration round the right knee increased in extent. On February 22 a haematoma on the right thigh with overlying oedema was noticed, and there was a further and more extensive bruising of the left thigh muscles (Figs. 1, 2, and 3).

Clinically the condition now was definitely scorbutic, and inquiry elicited the information that since childhood he

* Anisocytosis. † Considerable anisocytosis with many megalocytes. ‡ Anisocytosis and polychromasia.

patient had had a distaste for fruit and fresh vegetables amounting to a phobia, the sight of a tomato or an apple being enough to cause nausea. Most of the meat which he had at home was twice cooked in the form of puddings and pies, and his only source of vitamin C appeared to be potatoes. It was not at the time realized, however, that avitaminosis C could cause such a profound anaemia of a hyperchromic type, and it was thought that it was only a contributory factor in the production of this anaemia. The iron therapy was discontinued on February 19, and on February 22 and the ensuing days quantitative tests for scurvy were performed (Table III).

The decolorization time of intradermal 2:6-dichlorophenol-indophenol on February 22 averaged seventeen minutes, and the total urinary output of ascorbic acid in twenty-four hours was only 6.7 mg. Treatment was at once begun with ascorbic acid, 600 mg. daily by mouth. On February 25 urinary excretion was still deficient, and an extra dose of 1,000 mg. by mouth was given. The total output during the ensuing twenty-four hours, however, was only 12.9 mg. The red cell count had risen to 2,000,000 per c.mm.

On March 5 the haemorrhages into the hair follicles of the leg had completely disappeared, and the larger ones were absorbing satisfactorily. On this, the thirteenth day of treatment, the excretion test showed a greatly increased figure for the first time, the intradermal test having become normal on the fourth day of vitamin C therapy. On March 8 extra vitamin C, in the form of orange juice, was administered, and apparently saturation was achieved a week later, after three weeks' therapy and the administration of over 14 grammes of ascorbic acid; for on March 15 235 mg. of the test dose of 600 mg. were excreted. Throughout this period, on vitamin C therapy alone, steady improvement was made, the red cell count being 3,900,000 per c.mm. by March 16 and 4,400,000 by March 30. As by the latter date the patient's haematoma were completely absorbed, his joints normal, and his other scorbutic signs gone, he was discharged. With continued vitamin C therapy the blood count soon became normal.

Case II

This case makes an interesting comparison with Case I, for it presented more of the commonly described features of adult scurvy. But in spite of certain differences the two cases were obviously examples of the same disease.

The patient, a married man aged 65, had previously been very healthy. From 18 to 41 years of age he had been at sea, often on long voyages of eighteen months or two years. During this time he had seen men with scurvy, but his ships had always allowed rations of lime juice and fresh food. Only in the last four years had his diet become deficient in vitamin C, consisting mainly of porridge, milk puddings, bread and butter, fish, and eggs. His appetite had deteriorated, and at the time of admission was very poor, particularly for fruit, tomatoes, and the like. He felt generally unwell, but his chief complaints when first seen were of pain and swelling of the right knee for two months, and of progressive soreness and swelling of the gums for nine months. The latter had become so bad that he could eat soft food only.

CONDITION ON ADMISSION

On admission into Redhill County Hospital under the care of one of us (G. H. J.) the patient showed anaemia and wasting. The skin of the face, forearms, and hands was of a sallow muddy colour. The gums were striking (Figs. 5 and 6), being swollen, blue, and mauve, and bleeding very readily. The teeth showed marked caries and pyorrhoea, and there was a most unpleasant oral fetor. The right forearm showed a number of subcutaneous bullous haemorrhages, which had been caused by slight injuries a year before (Fig. 4). There were large ecchymoses on the knees, left shin, and left ankle. There were again many follicular petechiae on the shins and around and above the knees. The right knee was distended with fluid. Other symptoms revealed little of note, though there was some arteriosclerosis, and the blood pressure was 180/90. The tourniquet test was strongly positive, the whole forearm being smothered with large petechiae after five minutes of arm compression at 80 mm. Hg.

INVESTIGATIONS

Blood Count (8/7/38).—Red cells, 3,420,000 per c.mm.; haemoglobin, 67 per cent.; colour index, 0.98. White cells, 6,000 per c.mm.; reticulocytes, 0.8 per cent.

Marrow Puncture (15/7/38).—Megaloblasts, 1 per cent.; primary erythroblasts, 2 per cent.; late erythroblasts, 3.5 per cent.; normoblasts, 11.5 per cent.

Bleeding Time.—Less than five minutes.

Coagulation Time.—Three minutes (Wright).

It was unfortunately impossible to get a sample of gastric juice from this patient.

COURSE AND TREATMENT

The patient continued with a diet poor in vitamin C, but from his sixth day in hospital 600 mg. of ascorbic acid were given daily by mouth. By the end of a week's treatment his gums were much better, his bruises were much less marked, and his knee less swollen. After a fortnight's treatment his knee was still slightly swollen, but the gums and the skin were almost entirely free of haemorrhages. The tourniquet test by now was much less positive, fifty tiny petechiae being produced. On the fourth day of treatment there was a reticulocytosis (6 per cent.), but the anaemia again only improved slowly (Table II). As in the first case, however, the anaemia was completely cured as a result of vitamin C therapy, in this instance after about a month's treatment. At the time of the last blood count the tourniquet test was almost negative, only five minute petechiae being produced.

* At 2 p.m. on 25.2.38, a pinkish systolic and diastolic anaemia. † Slight anaemia.

The treatment given to this patient was 600 mg. of ascorbic acid daily by mouth. All other vitamin-C-containing food and iron-containing food was excluded from his diet as much as possible until July 27, when a liberal allowance of fresh fruit was introduced. The excretion of ascorbic acid in the urine was estimated daily (Table IV), and it was found that saturation was reached on the twelfth day of treatment and after the administration of 6.6 grammes of ascorbic acid. As might have been anticipated from the shorter history of deprivation, this case was less dehydrated in vitamin C than Case I. With the general improvement in the patient's condition his appetite improved, and when seen recently he reported that he was "eating like a horse" and taking plenty of fruit.

Discussion

There are many features of interest in these cases, and not the least is that they were married men with devoted wives. Schultz (1936) and others have drawn attention to the liability to scurvy of single and solitary men, but the first patient was most unwilling to come into hospital because only his wife was able to give him "the food that suited him." She had indeed, with the best will in the world, severely and carefully limited the vitamin C in his diet for many years! His extreme aversion to fresh fruit and vegetables, which appeared to have increased with the severity of the scurvy, was another interesting feature. After his scurvy had been successfully treated he was able to take fruit juice with a certain amount of relish.

The clinical features in these cases were, of course, quite typical: the sallow muddy complexions; the extravasations of blood behind the knees (Figs. 1 and 3) and around the ankle (Fig. 2); the swollen knee-joints; the oedema; the petechiae in the hyperkeratotic hair follicles on the legs (Fig. 3); and the spongy gums in Case II (Figs. 5 and 6).

Bondurant (1934), Schultz (1936), and Nisenson and Cohen (1937) have all recently reported similar cases, and among these and other recent ones the characteristic gum bleeding and mouth fetor occurred only occasionally. In the other cases teeth had been removed, and the most obvious evidence of scurvy was not therefore

prominent. In view of the recent importance attached to the discovery of latent scurvy as a cause of ill-health and its appearance after comparatively short periods of time in the dietary treatment of peptic ulcer (Mourne, 1938), it is interesting to observe from the first case the length of time during which scurvy will remain latent. It is fair to assume that for forty years at least this man had lived on a diet grossly deficient in vitamin C, and yet only for a few years had he had any symptoms. The first of these symptoms, dyspnoea, was presumably due to anaemia, and had been present increasingly for three or four years. In his case the haemorrhagic symptoms had only just appeared when he was seen, but Schultz's (1936) cases show that severe haemorrhagic phenomena may make scurvy evident before anaemia has developed.

The anaemia in this case was of peculiar interest, and because it proved deceptive to us we now propose to consider it in detail. The blood counts and their relation to the treatment given are shown in Table I. The megalocytic and hyperchromic tendency of the anaemia up to the time of vitamin C therapy is evident from this table and from the Price-Jones curve (see chart) of January 11. On January 11, before any treatment, the mean corpuscular volume was 113.6 cu (normal, 75.7 to 96 cu), and there was anisocytosis. A little later the sternal marrow showed a hyperplasia chiefly affecting the early red cells, and the gastric juice revealed an achlorhydria. The blood cells at this time showed also a considerable variation in density of staining.

Chart of Case I: Price-Jones curve, showing the megalocytosis before the beginning of treatment.

These findings are similar to those described in pernicious anaemia, but there was a persistent reticulocytosis (2.5 to 9 per cent.), and neither the blood count nor the reticulocytes gave any response to liver therapy. Iron, as was anticipated, also had no effect. That a megalocytic anaemia of this type might occur in scurvy was first

suggested by Mettler, Minot, and Townsend (1930), who found that in the severe anaemia of some scurvy cases there might be enough red cells larger than normal to suggest a diagnosis of pernicious anaemia. Nisenson and Cohen (1937) have described a severe case of scurvy, very much like Case I, with marked anaemia and a colour index of 1.16. Among eight cases of infantile scurvy Parsons and Smallwood (1935) report one case of megalocytic anaemia, while two of their anaemia cases were normocytic and orthochromic, and two were hypochromic. Three cases had no anaemia at all. Mettler, Minot, and Townsend state that of cases of clinical adult scurvy a third are not anaemic, while half the remainder are severely anaemic and half moderately anaemic. As a general rule they found an orthochromic normocytic anaemia in scurvy, and this type of anaemia, shown by the second case, has also been found by Bondurant (1934) and Wood (1935).

The anaemia of scurvy is attributed by Parsons and Smallwood to deficient oxygenation of the marrow. Vitamin C takes up oxygen and releases it in the tissues, and when vitamin C is deficient in the marrow the maturation of red cells is retarded by lack of oxygen. While the stage of maturation of normoblasts to erythroblasts is most usually disturbed, the megaloblast maturation to normoblast may be chiefly affected in some cases, as in the first case just described. This case, with a very low level of vitamin C in the tissues, showed in the marrow a great interference with the maturation of the early cells of the red cell series, and a severe megalocytic anaemia resulted. Case II, with a less marked vitamin C desaturation of the tissues, showed no definite interference with the maturation of the early red cells and only a moderate normocytic anaemia. Such findings suggest that there is some relation between the extent of vitamin C lack in the tissues and the point at which marrow-cell maturation is chiefly affected.

In cases of scurvy anaemia, vitamin C administration provokes a reticulocytosis (see Case II), but the high reticulocyte count in Case I before treatment is a curious finding, though it was a feature to a lesser degree (2.5 per cent.) in Nisenson and Cohen's megalocytic case. The hypochromic anaemias found in scurvy result from blood loss and an associated iron deficiency, and in such cases a partial response to iron may be expected.

Achlorhydria may be a contributory factor in producing scurvy, as was pointed out by Schultzer (1933): for vitamin C is only stable in an acid medium. Injection therapy is therefore preferable in such cases.

We employed as confirmatory of the diagnosis of clinical scurvy three tests which have been used to make the diagnosis of latent scurvy. These were the ascorbic acid saturation test of Abbasy (1935); Rotter's intradermal test with 2:6-dichlorophenolindophenol (Rotter, 1937); and the capillary resistance test. The position of these tests in relation to scurvy in general and to our cases in particular may be summarized briefly as follows:

I. THE ASCORBIC ACID SATURATION TEST OF ABBASY

In this test the patient is kept on a diet free of vitamin C, and after a short control period 500 to 1,000 mg. of vitamin C (ascorbic acid) is given daily by mouth and the amount excreted in the urine is estimated. The saturation point is usually reached when half the quantity administered daily is excreted, but even on vitamin-C-free diets some ascorbic acid is excreted by severe cases of scurvy (Schultzer, 1936). All Schultzer's cases excreted as much as 17 mg. daily, and one excreted 33 mg. under these conditions.

Our first case was given 600 mg. of ascorbic acid by mouth on all the days shown in Table III, except on the fifth day (February 25), when an extra 1,000 mg. was given, also by mouth. Fruit juice was added from March 8 to 14, and was discontinued for the excretion test on March 15. The table reveals several interesting facts, the first being the comparatively large amount of ascorbic acid excreted when the body was still as markedly desaturated as it was on the day preceding therapy and in the early days of treatment. Also interesting was the long delay of eight days before there was any appreciable increase in the amount excreted. In the last place, if

* Only a half-day's specimen.

50 per cent. excretion of administered ascorbic acid indicated saturation, our first patient was apparently just short of this point after three weeks' treatment. By then 13.6 grammes of ascorbic acid tablets had been administered and much more had been given in fresh fruit, a considerable difference from the 0.5 gramme to 2.3 grammes which Wilkinson and Portnoy (1938) find will saturate a normal person.

Case II, as previously pointed out, was much less deficient in vitamin C, and was saturated after eleven days' treatment and the administration of 6.6 grammes of ascorbic acid (Table IV).

2. PORTNOY'S INTRADERMAL TEST (1937)

In Table V the times of decolorization by Case I of an intradermal spot of the blue dye 2,6-dichlorophenolindophenol are charted. As described by Wilkinson and Portnoy (1938) 0.1 ccm. of a solution of the dye (2 mg. in 4.9 ccm.) was injected intradermally in four places. Normally the blue spots are decolorized within ten minutes, and this was the case in our healthy controls. But in cases of rheumatism, rheumatoid arthritis, and other infective conditions we found the time to be prolonged (up to thirty minutes in one instance). In scurvy it is usually much prolonged, and Case I at first showed average decolorization times of seventeen and twenty-one minutes. But after three days of oral ascorbic acid treatment the time became normal.

TABLE V

| Date | Average Decolorization Time of Intradermal Test* | Treatment (Oral Ascorbic Acid) |
|---------|--|--------------------------------|
| 22/2/38 | 17 | 100 |
| 23/2/38 | 21 | 100 |
| 24/2/38 | 7½ | 1,000 |
| 26/2/38 | 8 | 100 |
| 1/3/38 | 8 | 100 |
| 2/3/38 | 7 | 100 |
| 12/3/38 | 4 | 100* |

* Fruit juice also given from March 8

It will be observed by comparison of Table III with Table V that the cutaneous dye test shows a normal result much more quickly than the excretion test—that is, it becomes normal in the presence of vitamin C deficiency. This fact was further exemplified by Case II, the patient giving a normal result (three to six minutes) before any treatment. Inquiry revealed that in the week before admission he had taken two bottles of lime juice, his only appreciable intake of vitamin C in four years. It is possible that this was the cause of his normal intradermal test time, though he was still very deficient in vitamin C and clinically a clear case of scurvy.

3. THE CAPILLARY RESISTANCE TEST

This test has slight technical variations, and for the cases in this paper a pressure of 80 mm. Hg was sustained for five minutes. Dalldorf (1931) has shown that in the experimental scurvy of guinea-pigs a decreased capillary resistance is the first sign of the disease. Bourne (1938) has used the test to disclose latent scurvy during the treatment of peptic ulcers, but it must be remembered that normal people may at times give positive results to variable

small extents. The height of the blood pressure and the state of the vessels influence the results. For these reasons it is perhaps not surprising that Case II initially gave a far more extensive response to the test than did Case I. In Case II numerous large petechiae appeared over the whole forearm; in Case I there were about fifty petechiae in the ante-cubital fossa. In both cases the test results approached normal very early in treatment. In Case I the result was negative on the eighth day, and by then the skin petechiae elsewhere were almost gone. This early decrease in capillary permeability corresponding with the rapid clearance of the haemorrhagic manifestations has been commented on by Schulz (1936), and is the converse of Dalldorf's observation. In Case II the capillary response was a little slower, being almost negative by the fifteenth day and quite negative at the end of a month's treatment. Rather surprisingly in Case I it was found that on the thirty-fifth day of treatment the test was again definitely positive. Schulz (1936) has also commented on this variation in the result of the capillary resistance test in cases of treated scurvy. In this connexion it is interesting to note that Greene (1934) found a positive tourniquet test in 10 per cent. of healthy children and only a similar number of positive results in a group of children who might have been suspected of latent scurvy. He found variations in the test from time to time, and even a difference between the responses on the two arms of a normal subject.

Summary

Two cases of adult scurvy have been described which showed many of the classical features of the disease. The first case revealed a megalocytic anaemia not often associated with scurvy. A constant reticulocytosis, polychromasia, anisocytosis, and leucopenia were also observed in this case. A hyperplastic bone marrow showing many early red cells, a smooth tongue, gastric mucosal atrophy, and achlorhydria were further features of the case which simulated those of Addisonian anaemia. This case has been contrasted with a second case in which the anaemia was of the more usual orthochromic and normocytic type, and in which the characteristic gum lesions made the diagnosis evident, although the latter was otherwise a less severe case. An attempt has been made to find some relation between the clinical and haematological differences in the two cases and the different vitamin C levels demonstrated in their tissues by an excretion test. The initial differences of tissue vitamin C levels in the two cases seemed to be related to the lengths of their respective periods on scorbutic diets. The value of the intradermal test and the capillary resistance test in the diagnosis of scurvy has been discussed.

In the first case a megalocytic anaemia failed to respond either to liver or to iron, but in both cases the anaemia was cured solely as a result of vitamin C therapy. The clinical pictures improved more rapidly than the blood pictures. The comparative slowness of the responses in the blood might have been ascribed, to defective absorption of the orally administered vitamin C as a result of an atrophic alimentary mucosa and lack of gastric acid. But the early disappearance of the superficial manifestations of the disease and the early normality of the intradermal test make this explanation unlikely. The great ascorbic acid desaturation of all the tissues, particularly in Case I, is the probable explanation of the slowness of the blood response. In Case I it is evident that the anaemia was much the earliest manifestation of the disease, so that it is not surprising that it should have been the last to disappear. The history of this case showed that

vitamin-C deficiency must have been present for many years before the scurvy became clinically manifest.

We are indebted to Dr. Janet Vaughan, Dr. R. G. MacFarlane, and Dr. G. A. D. Haslewood for help with the investigation of the first case, and to Dr. J. H. Patterson for similar assistance with the second. The first case is published by permission of the Chief Medical Officer of the L.C.C., and the second by permission of the Chief Medical Officer of the Middlesex County Council.

Clinical Memoranda

A Tumour of the Male Breast

This case, recently under my care, appears to be worth recording by reason of the very interesting differential diagnosis.

CLINICAL HISTORY

On October 4, 1937, I admitted a man about 35 years of age, complaining of a lump in his left breast. His attention had been first drawn to it eight months earlier by pain, though the pain had at no time been at all severe. Since then the size of the tumour had slowly increased. He also complained of pain in the right knee and ankle. He was thin, and had evidently lost a good deal of weight.

On examination there was an obvious lump in the left breast, mainly in the right upper quadrant. It stood out about three-quarters of an inch from the chest wall, was roughly oval in shape (2½ in. by 2 in.), and the margins were ill defined. There was no change in the skin. On palpation the tumour was of firm consistence and did not fluctuate. It was attached to the deeper structures, being fixed to the chest wall, but not adherent to the skin, which was freely movable over it. The lump was not at all tender. In one part over the third rib there was just palpable a very narrow ridge of bone standing up one-eighth of an inch or less, and running across the rib. In the axilla were two enlarged, firm, painless, discrete, and freely movable glands, the largest of which, the size of the shell of an almond, it was easy to take up with the fingers. There were one or two similar but smaller glands in the subclavicular region, but the clavicle appeared free above. There were no abnormal physical signs in the chest, and the patient had no cough. On admission he had a temperature of 99.8° F., which responded to quinine at once. (I had treated him for malaria about two weeks previously.)

DIFFERENTIAL DIAGNOSIS

The diagnosis appeared to lie between tuberculosis and carcinoma, although a sarcoma and gumma had also to be borne in mind.

Against carcinoma there were the following points: (1) Carcinoma is reputed to be very rare amongst the natives,

although in my nine months out here I have had several cases. (2) The first symptom being pain, though at no time was pain a marked feature, and there was a complete absence of tenderness on examination. (3) The presence of the small bony ridge. In favour of carcinoma there were: (1) The general impression on examining the tumour. (2) The consistency and mobility of the glands. A supporting factor was the presence of pain in the knee and ankle, possibly of metastatic origin. There was no local abnormality to be discovered.

Against tuberculosis there were: (1) The absence of pyrexia save for that which responded to the quinine. (2) The absence of fluctuation. (3) The absence of any evidence of perilymphadenitis. (4) No evidence of any other focus of infection. In favour of tuberculosis there were: (1) The presence of the bony ridge, suggesting a bony origin of the tumour. (2) The extreme frequency of all types of tuberculous infection in this part of Central Africa. (3) The deep attachment with no skin involvement, though a sinus might have been expected. (4) Pain being the first symptom.

OPERATION

A radical operation was decided upon. The axilla and sub-clavicular region were cleared of infected glands. No evidence of periglangular reaction was found. On turning the pectoralis minor forwards and inwards a tuberculous abscess was found in the muscle, larger in size than a large walnut: it was in direct communication with an abscess in the third rib. There was a small bony ridge to the left margin of the opening into the bone. As the general condition of the patient contraindicated a partial resection of the rib the bony cavity was scraped and filled with bipp. There was an uneventful recovery.

Discussion

I consider that the presence of the bony ridge was of important diagnostic significance. I shall be interested to learn if the presence of such a ridge, due presumably to the hyperosteoitic reaction sometimes found in tuberculous infection of the bone, has often been noticed in these lesions of the ribs. A blood count might have helped in the diagnosis, and a radiograph certainly would have, but there are no facilities for this out here.

Drainage of Pelvic Abscess in Acute Appendicitis

In cases of acute appendicitis with rupture of the appendix it is common to find, especially in late cases, that an abscess has formed in the bottom of the pelvis. This abscess is most safely and conveniently drained by the introduction of a tube through a small suprapubic incision.

I have devised a simple, quick, and easy method of doing this, as follows:

Place an ordinary sewing thimble on the forefinger of the left hand and introduce it through the wound made for the removal of the appendix, keeping it close to the anterior abdominal wall, till the tip reaches the central suprapubic position. The finger is now pressed against the anterior abdominal wall, and an incision, about three-quarters of an inch long, is made over and down to the thimble, which can be felt under the skin. The thimble is now pushed up through this incision and removed. A drainage tube is then placed on the tip of the left forefinger and guided by it down to the abscess cavity. By this method there is no danger of incising distended bowel, distended bladder, or the operator's finger.

Reviews

RESPIRATION

Adventures in Respiration: Medals of Asphyxiation and Methods of Revivification. By Yandell Henderson. (Pp. 316; 15 figures. 3 dollars.) Baltimore: Williams and Wilkins; London: Baillière, Tindall and Cox. 1938.

This book contains two very interesting photographs of the Pike's Peak Expedition of 1911, showing some of the members busy with scientific observations at high altitudes. One of the members is the late John Scott Haldane, to whose memory the book is fittingly dedicated. It was during talks on respiration while on that expedition that the ideas set forth in the present book began to take shape. In 1885 Miescher or Haldé wrote, "Over the oxygen supply of the body carbon dioxide spreads its protecting wings," but it was not until 1905 that the pressure of carbon dioxide in the arterial blood was proved—by the Oxford school under Haldane—to be the main controlling mechanism of respiration. Throughout his long scientific career Professor Yandell Henderson has also been engaged with similar researches concerning carbon dioxide and other gases, and he is part-author of the standard book *Noxious Gases*. In these labours he has been assisted particularly by Dr. Howard W. Haggard, and the present book is written chiefly around some of their joint researches, many of them dealing with public health problems investigated for the U.S.A. Bureau of Mines. This work has led Professor Henderson towards two new conceptions, which are now dealt with in detail. One is that of muscle tonus as a major factor in the control of the circulation and of failure of muscle tonus as a cause of failure of circulation. He considers that carbon dioxide at a normal pressure in the tissues is necessary for normal muscle tonus, which is required to maintain normal venous pressure, and this in turn helps to maintain a normal circulation. The other conception is that of "acarbina" (lack of carbonates in the blood) as induced by "hyperpnein" (hypothetical substance or condition produced by muscle contraction and stimulating the respiratory centre) in place of "acidosis" induced by lactic or other acid. He thus includes two stimulants for the respiratory centre—namely, carbon dioxide and "hyperpnein." Hyperpnoea removes not only carbon dioxide from the blood but also bicarbonates, which pass into the tissues.

The book is mainly of interest to researchers working on the study of respiration. When dealing with acclimatization to high altitudes the author unduly neglects all other systems, particularly the cardiovascular system, which really cannot be so precisely separated from the respiratory or any other system. The term "acclimatization" is also used rather loosely. Low oxygen pressure experiments on mammals and observations on natives attempting to live continually near 20,000 feet in the Andes prove that there can be no complete acclimatization much above 20,000 feet. Professor Henderson also deals rather leniently with the theory of oxygen secretion by the lungs, since studies of oxygen pressures in the tissues during prolonged exposures of mammals to low oxygen pressure in the air or to chronic carbon monoxide poisoning prove that there is no active secretion of oxygen by the lungs. He also says—rather courageously—that there is no chronic carbon monoxide poisoning in man, but there are many animal experiments dealing with this state—that is,

continued exposure to non-fatal concentrations of carbon monoxide. Further, the value of oxygen administration near the summit of Mount Everest seems to us to be underestimated.

For the medical practitioner there are important and interesting facts scattered throughout the book. A disadvantage is the absence of a short summary to each chapter, which would so much help the clinician. To sum up recommendations: carbon dioxide should be administered temporarily—either with fresh air or pure oxygen—when there is depression (without paralysis) of the respiratory centre—for example, in carbon monoxide poisoning and asphyxia neonatorum. Also it should be given to remove anaesthetics after operations—that is, to prevent post-operative complications; for example, atelectasis of the lung and pneumonia. Of course, rebreathing is used in anaesthesia to prevent over-removal of carbon dioxide from the blood. Professor Henderson also recommends carbon dioxide to help to preserve muscle tonus in shock, but it is harmful in conditions which resemble that produced by injections of acids. Moreover, carbon dioxide is useless in complete paralysis of the respiratory centre: here oxygen should be insufflated into the lungs. The author recommends caffeine (coffee) and not lobeline as a respiratory stimulant, and gives his support to strychnine as a therapeutic measure in loss of muscle tonus (shock).

The bibliography is complete as regards the author's own publications, around which the book is written. Search in the text for the proper authority for any particular statement is thus not always easy, and there are few dates in the text to help application of the references which are given in the bibliography. The book is written in the author's usual vigorous and very entertaining style, and recalls many interesting scientific incidents and adventures of peace and war.

DISEASE AND ITS SOCIAL SETTING

Cliniques de Médecine Sociale à l'Hôpital Saint-Fient. By Dr. René Sand. (Pp. 187. 20 fr.) Brussels: Jean Vromans. 1938.

Those who were interested in Dr. René Sand's suggestive and informative book *L'Économie Humaine* (reviewed in these pages on October 24, 1932, p. 732) or in its English translation *Health and Human Progress* (reviewed on December 21, 1935, p. 1211) will welcome this book. It is the obvious sequel to the first, for it shows how Dr. Sand has put into practice his doctrine that sociology and clinical medicine are closely related. Dr. Sand, in addition to being secretary-general of the Public Health Ministry of Belgium, is professor of social medicine (the first of the kind anywhere) in the University of Brussels. These lectures have been published as an incentive to others who may believe, as he does, that the practical application of his doctrine is urgently needed.

In his former book Dr. Sand showed the great part that medical science is playing in the science of sociology, and argued that it could do much more if the knowledge already acquired could be systematized and taught as an essential part of clinical medicine. His dual position has enabled him to show how it can be done. The ten lectures described in this book were given to his students, with the collaboration of a clinician. The intention is not so much to contribute to the teaching of medicine or of sociology as to show, by taking concrete examples, the connexion between certain maladies and the social conditions of the patients. The subjects dealt with are: anaemia due to poverty, pulmonary tuberculosis, lupus, Pott's disease in adults, pregnancy and syphilis in

unmarried women, diabetes necessitating a change of employment, rheumatism, weakly children, mentally deficient children, and syphilis and hereditary syphilis.

The effect of reading the studies of the individual cases discussed reminds one of what might be the result of an examination of the case in this country by a super-almoner and a medical man of broad sympathies and clinical acumen. The lecturer gives what he calls a "social diagnosis" followed by "social treatment" in the course of which the students are informed of the various social measures at the disposal of the doctor. It is not suggested that the doctor should take the place of the almoner or the public assistance officer, but that he should realize that all his medical prescriptions may be of little effect if the social factors at work are not evaluated and dealt with. Dr. Sand ends his stimulating lectures with these words to his students: "Though we have had for more than fifteen years an organized social service covering the whole nation, it is evident that a long education will be required before its principles penetrate the ensemble of our public assistance and private charity. I trust that you will desire to contribute to this education by your personal action."

THE VIRUS OF LYMPHOCYTIC MENINGITIS

La Maladie d'Armstrong: Chorio-méningite Lymphocytaire. Une Nouvelle Entité Morbide? By Boris Kreis. (Pp. 160; 14 figures. No price given.) Paris: J.-B. Baillière et Fils. 1937.

The discovery by Armstrong and his associates that certain cases of benign lymphocytic meningitis in man were due to a virus which they had previously found as a spontaneous or accidental infection of laboratory monkeys gave fresh interest to this disease. Dr. Boris Kreis has now collected all the known facts about this virus, as well as his own studies of it, in a small monograph. The virus has two interesting characteristics. So far as we know it is the only virus which may be found in the cerebrospinal fluid of man. It is also the only virus which may be communicated to man under natural conditions from mice. The evidence for the latter is not conclusive, but there seems to be little doubt that it occurs as a natural epizootic in both white and grey mice, and it can be found in the urine of infected mice. Other laboratory animals are less susceptible to infection, and the fact that some batches of mice show a varying degree of immunity to the virus makes its study more than usually difficult.

The relation of the virus to human disease is still uncertain. Although it, or a closely similar virus, has been recovered from human cases of lymphocytic meningitis in England, France, and North Africa, as well as in America, less than twenty strains have so far been isolated, and in the majority of cases which show the clinical picture of benign lymphocytic meningitis, and which have been examined, the cerebrospinal fluid has not contained any virus. It seems probable that these cases may be due to more than one type of virus; those of mumps and of "louping ill" have been definitely incriminated in some cases, and the relation of others to epidemics of influenza suggests that the recently discovered virus of this disease may be sometimes responsible.

Dr. Kreis has tried subcutaneous inoculation of this virus in the treatment of two cases of general paralysis, and has shown that it is possible to infect human beings, but this seems to have no therapeutic value.

DISEASES OF THE CHEST

Introduction to Diseases of the Chest. By James Maxwell, M.D., F.R.C.P. (Pp. 328; 95 figures. 12s. 6d. net.) London: Hodder and Stoughton. 1938.

The responsibility attached to the writing of a textbook for medical students is a heavy one, for the undergraduate of to-day is the doctor of to-morrow and of many years afterwards, and the general practitioner finds it hard to keep abreast of developments and changes in medical science and practice. It is all the more important, therefore, that the student should have impressed upon him early in his career correct basic principles and a sense of proportion. This is just what one would expect in an introduction to a special branch of medicine, particularly when this concerns a branch that has witnessed so many fundamental changes in recent years as has diseases of the chest. We feel that Dr. Maxwell has not been altogether successful in his attempt to do this, chiefly perhaps because he has tried to be too comprehensive with an eye to the student's examination requirements. For this purpose the book should serve admirably. On the other hand, it contains, apart from much sound clinical advice based on the author's experience, several statements, repeated in textbook after textbook, that have never been scientifically confirmed, and classifications that are not only useless but may be misleading in actual practice. Again, though the teaching of pathology is not the prime purpose of the book, sound pathological notions are essential for a proper understanding of the clinical aspects of disease. In this respect Dr. Maxwell is not always quite up to date. Finally, the illustrations, which consist almost entirely of skiagrams reproduced on a small scale, may confuse rather than assist the student because of the inadequate captions and the absence of their detailed explanation in the text.

Despite the above criticisms Dr. Maxwell's book should be of value, for it succeeds in its purpose—"to present to the student the clinical aspects of respiratory disease, to correlate the history with the physical examination, and to indicate the various special investigations which are likely to assist in making an assured diagnosis."

A METHOD OF ANATOMY

A Method of Anatomy: Descriptive and Deductive. By J. C. Boileau Grant, M.B., Ch.B., F.R.C.S.Ed. (Pp. 630; 564 figures. 27s. net.) London: Baillière, Tindall and Cox. 1937.

This work, by Dr. Boileau Grant of Toronto, is a departure from the traditional precepts of the older textbooks of anatomy. The author has studied the subject principally from the mechanical standpoint, and has sought to correlate anatomical facts by considering their mutual relations and purpose. In this respect he has been specially successful; for example, in his descriptions of the articulations, and in his account of these and of other systems, such as the skeletal and muscular, he has contributed many useful new observations which are of practical importance. The general trend of the book is confined to the spatial relationships of one structure to another, with brief statements on the significance of these contacts.

Unfortunately, though the descriptions in the text are for the most part regional, the general appearance of the regions as a whole are not depicted in such a way that a student, approaching the subject for the first time, would be able to recognize easily the individual structures or organs that he is investigating. Thus, there are very few illustrations giving the complete picture of such regions as

the back, the front of the forearm and palm of the hand, or the extensor region of the leg and dorsum of the foot. A complete view of such muscles as the trapezius and latissimus dorsi, or of the gluteal region after reflection of the gluteus maximus muscle, is invaluable. Since these illustrations usually form the first introduction to the student's general conception of the parts under consideration and serve as an example of how the parts should be displayed in a good dissection, their absence must be regarded as a grave defect. Moreover, the technique of the illustrations, as a whole, is much below the modern standard of achievement, and there are numerous crudities of expression—for example, U.-G. TRACT & CO., or G.-I. TRACT & CO.—both in the legends and text, which, combined with a lack of uniformity in spelling, gives an impression of carelessness, in place of one of the most valuable side-issues which arises indirectly from a sound training in anatomy—namely, a scrupulous regard for exactitude in observation and respect for niceties in literary expression.

There are also some very important limitations in the scope of the book. Thus, we find no description of the brain or spinal cord; and there is little or no indication, either in the figures or in the text, of the internal structure of such organs as the spleen, liver, salivary or ductless glands. The surroundings of these organs are accurately described, but the contained organ appears to be regarded as a "cast of the mould," and the reader is, in one instance, informed that if (he) "makes a careful study of the mould (he) need not devote time to the cast which is but a counterpart of the mould." A "careful study" is, however, advocated and described, for example, of the membranes which surround the brain and of the capsule of the parotid and other glands along with the related nerves and vessels; and if it is borne in mind that the book deals with the form rather than with the internal structure of the organs described it may be recommended as a help to the comprehension of the subject from the mechanical standpoint and as a supplement to those general treatises which give a more complete account of the structure and development of all the important organs and tissues.

Notes on Books

The sixth supplementary volume of HEFFTER'S *Handbuch der Experimentellen Pharmakologie* contains two articles: one by Professor Gessner of Halle, which deals with animal poisons, while the second, by Professor George Bayer, describes the alkaloids of ergot. The subject of animal poisons is a very wide one, and the author has summarized briefly, in about eighty pages, the important advances that have been made since 1924, when Professor Faust reviewed the subject in Heffter's textbook. The article will be found very useful for reference by those working on such problems as the pharmacology of snake venoms. Ergot was previously dealt with in Heffter's textbook in an article written by the late Professor A. R. Cushing in 1914 and published in 1924. Professor Bayer contributes an authoritative review of the chemistry and pharmacology of the alkaloids of ergot, on which he has worked for more than thirty years. These alkaloids have presented peculiar difficulties both to chemists and to pharmacologists. Tarret in 1875 isolated a crystalline alkaloid from ergot, but it was not until 1936 that the most important alkaloid—namely, ergometrine—was isolated. Similarly, the pharmacological action of ergotoxine was determined in 1906, but the action of ergometrine was not demonstrated until 1932, although it would now appear that the action of ergot in child-

birth, upon which depended its introduction into clinical use, is due more to the ergometrine than to the ergotoxine content. Professor Bayer gives a full account of the pharmacological evidence, which, owing to this slow development in knowledge, is confused and often contradictory. The monograph concludes with an article on the history of ergotism. Professor Bayer's clear review of this difficult subject, with its long and confused history, is of great value. The volume is published in Berlin by Julius Springer at RM. 30.

Drugs, their Use and Abuse (Kegan Paul, Trench, Trubner and Co., 7s. 6d.), by LOUIS LEWIS, is an English translation of the second German edition of *Phantastica*. The author is renowned for his encyclopaedic knowledge of drugs and their history. The volume under review deals with the drugs of addiction, which the author divides into five classes: euphorica—for example, morphine and cocaine; phantastica—for example, mescal and cannabis indica; inebriantia—for example, alcohol and the anaesthetics; hypnotica—for example, chloral hydrate and veronal; excitantia—for example, coffee and tobacco. A special feature of the volume is that it gives an account of the effects not only of the well-known drugs of addiction but also of rarer varieties, such as mescal binisteria, loco weed, etc. It provides interesting and easy reading, since the author gives many accounts of the strange habits of peoples in all parts of the world, and the translation has been carried out very successfully.

Preparations and Appliances

IMMERSION AUTOCLAVES

Messrs S. Maw, Son and Sons, Ltd., have devised a simple apparatus wherewith moist heat at temperatures above 100° C. can be applied to instruments such as syringes or to vessels containing solutions in order to ensure complete sterilization. It consists essentially of a strong metal cylinder with a pressure-tight lid into which a small quantity of water (about one-thirtieth of its total capacity) is introduced as well as the material to be sterilized. This is completely immersed in glycerin, which is raised by a Bunsen flame or otherwise to a temperature of 115° to 116° C. and maintained at this for the requisite time, which is usually about half an hour. The apparatus is made in three sizes, the smallest taking a 1 c.c. syringe, the second a large syringe or other instrument of corresponding size, and the third being intended for vessels containing solutions. A heating-bath is also available, intended chiefly for use with the largest size, in which a temperature of 115° C. is automatically maintained by the boiling and recondensation of a mixture of water and glycerin in certain proportions.

ELECTRIC HEATING PAD

An electric heating pad which would seem to have a variety of medical and nursing applications has been introduced into this country. A solidly constructed switch, so arranged that it can be altered with certainty by touch alone, is incorporated in a strong flex connecting the pad to the source of electric current. Four thermostats form part of the pad itself, and when the switch is turned to "low" the temperature of the entire pad is maintained at approximately 115° F. When the switch is at "high" the temperature is in the neighbourhood of 185° F., and with the switch in the "medium" position a temperature of 150° F. is maintained. The pad is of a convenient size, and is soft and flexible enough to conform comfortably to the contour of any part of the body to which it may be applied. The pad is known as the "Universal positive control automatic three-heat pad," and is obtainable from L. G. Hawkins and Co. Ltd. of 30-35, Drury Lane, W.C. to whom all inquiries should be directed.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 15 1938

A MATERNITY SERVICE FOR NEW
ZEALAND

Early last year the Government of New Zealand appointed a committee of inquiry into maternity services in that Dominion. Its report, which has recently been published, is worthy of attention here as well as in the country of its origin. Part I of the report—three-fifths of the whole—contains an extensive and careful survey of the available facilities for the supervision and conduct of maternity, district by district (forty-eight in all) throughout New Zealand, together with recommendations for making good such deficiencies as were found to exist. Part II, which includes a brief history of the development of maternity services in New Zealand from 1882 to 1937, is largely occupied with the discussion of more general questions. Four or five of these have an interesting bearing upon similar discussions here. It has to be borne in mind, however, that conditions are by no means identical in the two countries. In New Zealand distances are greater, transport is more difficult, and the population much more sparse; social customs differ in several respects, and the routine and distribution of medical practice are not quite the same. Moreover, there is only one university and medical school for the whole of the Dominion—that in Dunedin—and hospital administration is quite different from that in Great Britain. Though these considerations may easily and properly give rise to divergencies of view, the answers given in the report to certain questions may be of value in both countries. What should be the respective roles of the doctor, the midwife, and the nurse in any maternity scheme? Is hospitalization or domiciliary attendance at confinement the better method? Should the general practitioner be able to continue his attendance and responsibility while the patient is in hospital? How far is it desirable to make the relief of pain in childbirth a first consideration? How can the training of the midwife, the maternity nurse, and the medical man best be provided for? These are not, of course, the only questions dealt with in the report. Among others, the problem of domestic help and the Maori problem are considered, and there are clear indications that the committee would like to make the provision for maternity an integral part of a national health insurance system.

The committee wisely remarks that it is "not impressed with the arguments of those who contrast the midwife system at its best with the doctor service at its worst." It is more concerned to decide which system at its best offers the fullest advantages, and concludes that, "although the midwife system is giving a safe and efficient service, the combined system of doctor and nurse attendance can give a still more efficient and more satisfying service." Its unanimous opinion is that a doctor should from beginning to end be definitely responsible for each case, and should be available to attend during labour if sent for by the midwife or nurse in the event of any difficulty or abnormality. Further, with the exception of two of the medical members, who think that the proposal would not be feasible in many rural areas, the committee would require the doctor to attend at certain stages of the confinement whether sent for or not. It seems that already in New Zealand three-quarters of all cases are attended by both doctor and nurse, and, except in England, this method is tending to become increasingly that on which organized maternity services are based. Some 82 per cent. of the total number of confinements in the Dominion take place in maternity hospitals, and this percentage tends to increase. It is not surprising, therefore, that the committee favours institutional rather than domiciliary attendance. It regards the former as being on the whole more efficient and less expensive to provide, apart from capital charges. There are, however, provisos to these conclusions. Every hospital must be of the highest efficiency or it may become a danger. The hospitals must be graded and well placed. They are declared to be less expensive to maintain only in comparison with the services of two nurses and domestic help in the home of the patient, and not with those of the peripatetic midwife. The conduct of midwifery by the latter, the committee declares, would not be tolerated in New Zealand. A further condition of hospitalization—and this is of the utmost importance—would be that the general practitioner in attendance on the patient should be able to continue that attendance in the institution. The committee is emphatic about this on several grounds, and though (with the exception of the chairman) it would prefer a "close" staff for the larger hospital in each of the four cities—Wellington, Auckland, Christchurch, and Dunedin—which undertake the training of midwives as distinguished from maternity nurses, even there it would establish other hospitals in which the general practitioner would attend his own patients. Much attention is given in the report to the relief of pain in labour. Though the committee appears to think that in private practice more care is given to this in New Zealand

than elsewhere. it states that this is rare in the public hospitals, and the majority of the committee wish that there should be greater provision for it. This, indeed, is one of the reasons why it favours the attendance of a medical practitioner at each confinement, though it would be prepared to extend the powers of midwives and nurses to administer at least sedatives and analgesics under the direction of, though not necessarily in the presence of, a doctor.

The training of midwives, maternity nurses, and medical students in midwifery is sufficiently discussed for the purposes of the report. That there are difficulties and inefficiencies in such training is clear; and those relating to medical students appear to be much the same as in Great Britain. Though in some parts of the country it is essential that every practitioner should practise obstetrics, the process of partial specialization in such practice is proceeding in the Dominion as elsewhere. The committee wishes to facilitate and perfect this, for it does not think it well, even if it were possible, that maternity practice should be for the most part in the hands of the obstetrical specialist. Successful midwifery, it remarks, is not his prerogative: "It is a field in which the general practitioner may, and frequently does, excel; and it is on the men and women who have devoted time and means to the development of obstetrics as a branch of general practice that the safety, health, and happiness of the child-bearing woman must, in the long run, depend." Finally, there is one pronouncement on the economic aspect of the matter which will be welcomed by practitioners in this country. The committee is "satisfied that, taking into consideration the range of service involved, the responsibility and the exacting nature of the work, and the great additional demands of modern ante-natal and post-natal care, the medical fees in midwifery practice are moderate and in some cases quite inadequate. Thus, while the total costs when paid by the individual may appear considerable, the charges for the various items of the service are by no means excessive."

THE STATISTICS OF WAGES

In his very important book, *The Human Needs of Labour*, reviewed in our issue of May 22, 1937 (p. 1074), Mr. B. Seebohm Rowntree gave weighty reasons for thinking that the cost of supporting a family consisting of father, mother, and three dependent children and the cost of supporting an adult independent woman worker were data of fundamental sociological importance. By means of a careful statistical analysis he showed that, though the most frequent existing family was not

of the size mentioned, when consideration was given to families of different sizes and to the difficulty of arranging family allowances, it was desirable to choose an over-all average in the way he had done. The interest and importance of the case of independent women workers hardly need a gloss. It follows that a computation of the numbers of male adults in occupations which do not enjoy average earnings equal to Mr. Rowntree's estimated minimum amount, and of the numbers of women employed in occupations not providing an average above the minimum for independent females, would be a useful addition to knowledge. We cannot, of course, say, because the average wages of, for instance, men aged 21 years or over employed in cotton weaving were 49s. 6d. a week in 1935, and Mr. Rowntree's minimum was 53s., that the whole population concerned—namely, these workers and their dependants—were necessarily underfed. Some of the workers may have had no dependants. Even if all were married men with families, some will have earned more than the average, unless every man earned precisely the same wage. But we can safely believe that, unless the composition of the population by age and civil state were extremely abnormal, an average wage below the minimum implies much hardship, to use no harsher term. Similar remarks apply to wage statistics of women aged 18 years and over; this group must include some who are not independent workers in Mr. Rowntree's sense.

Mr. Jürgen Kuczynski in his book *Hunger and Work*¹ has estimated the numbers of men and women in a large number of occupations whose average earnings do not reach the minima, and the results should be of definite value in sociological research. He has been obliged to base his calculations on sampling inquiries made by the Ministry of Labour, and allowance must be made for the incompletely representative character of the sampling, particularly the over-representation of large firms. Mr. Kuczynski's figures may well be taken as indices of unsatisfactory conditions, and from the census returns of occupied persons in 1931 it might be possible to obtain weighting factors to allow for differences in age composition and proportions of married men in different occupations. Mr. Kuczynski has in fact provided further data of value in a complete study of the condition of England. Mr. Kuczynski himself thinks he has done more: that he has proved that "10,000,000 working men, women, and children are living under such conditions that they cannot even keep fit for work, they are not able to recuperate completely from the exhausting work half

¹ *Hunger and Work: Statistical Studies.* By Jürgen Kuczynski. (London: Lawrence and Wishart. 3s. 6d.)

of them are continuously doing, and they have to spend more strength than they can get back through the purchasing power they earn." This estimate is, we think, little more than guesswork; in spite of a friendly hint from a trade union official that an average is, after all, an average. Mr. Kuczynski is emotionally convinced that, if one assumes that all persons in groups whose average earnings are below a certain minimum earn less than that minimum, the error is compensated by neglecting the numbers of persons in groups earning on the average more than the minimum who receive less than the group mean. Those who cannot share this faith may be tempted to dismiss the book as mere rhetoric. It does indeed contain much very bad rhetoric. But, if we use the arithmetical results as *indices*, they are significant contributions to knowledge and deserve most careful scrutiny. Medical readers should have no difficulty in separating the wheat from the chaff.

UNEXPECTED SCURVY

A revival of interest in Antarctic adventures—perhaps stimulated by the republication last year of Mr. Cherry-Garrard's *The Worst Journey in the World*—brings to the fore once again the problem of what part scurvy played in the final tragedy of March, 1912. It seems almost unbelievable in these days, when vitamin C can be easily synthesized, that in August, 1911, Dr. E. L. Atkinson, surgeon to Captain Scott's last expedition, could express the view that the cause of scurvy was tainted food, producing "acid intoxication." Yet knowledgeable as the public and the medical profession have now become about the cause and cure of scurvy, the disease still occurs in unexpected ways, as Dr. G. H. Jennings and Surgeon Lieutenant A. J. Glazebrook—it is appropriate that the Navy should still display interest in this disease—record elsewhere in this issue (p. 784). It is realized that single men living alone, often with dietetic habits that are peculiar from choice or necessity, may become scorbutic, and there is a similar risk in the dietetic regime prescribed in the treatment of peptic ulcer. But both patients described by Dr. Jennings and Surgeon Lieutenant Glazebrook were married men with devoted wives. It is particularly interesting that one patient, whose wife had for years carefully limited his vitamin C intake, was able to take fruit juice with a certain amount of relish when his tissues had become saturated as a result of massive dosage with ascorbic acid. "The clinical features in these cases were, of course, quite typical," state the authors, but perhaps this is wisdom after the event, for a study of the case records and details of treatment of Case I shows clearly that the combination of a megalocytic anaemia, bone marrow hyperplasia, and achlorhydria led to a provisional diagnosis of pernicious anaemia. After liver therapy had failed, the finding of occult blood in the stools suggested a neoplasm. It was only when further spontaneous haemorrhages into

various parts of the body occurred that the diagnosis of scurvy was made. The response to ascorbic acid was dramatic, full saturation of the tissues being obtained after three weeks with 14 grammes of ascorbic acid in all. The second patient, after escaping scurvy in over twenty years at sea on long voyages, despite his seemingly satisfactory home conditions, appears to have drifted into a dietetic programme which was grossly deficient in vitamin C. Here the diagnosis was prompt and the treatment completely effective within about a month. Besides serving as a reminder that scurvy must still be considered in the differential diagnosis of obscure anaemic and haemorrhagic states, this contribution also usefully analyses the various diagnostic aids available. But even if these give some indication of the degree of vitamin C deficiency present they would not appear as valuable in the absolute diagnosis as a history of a scorbutic diet and the effect of treatment, now happily possible in a simple and concentrated form. With tablets of ascorbic acid available in 1912, Polar history might have contained one more happy ending.

SEEPAGE IN POROUS SOILS

In view of the importance attached to the possible pollution of water supplies by seepage the experiments recently carried out by members of the Field Research Laboratory of the Alabama State Department of Health¹ are worthy of close attention. These experiments, conducted with extreme care, were fostered by the Health Division of the Rockefeller Foundation, and although the results in many respects run counter to preconceived notions and commonly accepted statements they are not on that account alone to be lightly set aside. The object of the present investigation was to determine over a prolonged period the nature, course, and characteristics of the seepage flow from a pit latrine situated in porous (sandy) soil in a river valley, and it was in fact a continuation of similar previous studies.² The experimental source of pollution was a privy pit constructed to bottom in about a foot of ground water and used continuously by a family of nine persons. The results of elaborate investigation of the physical, chemical, and bacterial characteristics of the surrounding soil having previously been recorded, concentric arcs of small tube wells were made around the pit, from which samples of the ground water were drawn for analyses. Contrary to current theory, it was found that traceable pollution did not travel radially in all directions but formed a diminishing "tail" in the direction of the ground-water flow with practically no extension up-stream, and, further, that the bacterial stream formed a defined cone within the chemical stream of less diameter and much less length—roughly about one-tenth. The tracing of faecal organisms was made the subject of special study, and it was found that the anaerobes (for example, *Cl. welchii*) penetrated much further than the aerobes—up to fifty feet—while the *B. coli* were not found beyond ten feet, and laterally not beyond

¹ *J. infect. Dis.*, 1938, 62, 225.

² *Ibid.*, 1937, 61, 148, 270.

five feet. The suggestion offered in explanation of the curtailment of the bacterial cone is that the organisms do not penetrate by growth in the soil but are mechanically carried in the flow. In time the soil in their path becomes clogged by gelatinous material, which forms an effective barrier, the process, in fact, being comparable to the "ripening" of a bacterial filter. At all times the pollution flow was found to be enveloped by fresh water. At times it would "swing" laterally with oscillations of the ground-water flow, increasing in width owing to lag and becoming correspondingly more shallow, but tending always towards its former shape. In a supplementary investigation the vertical seepage from a privy pit on top of a cliff face was undertaken, and here again the spread of pollution was remarkably limited. If the pit was kept dry, faecal organisms could not be found at one foot below; if it was exposed to saturation by rain *B. coli* were found at three but not at four feet; and if the pit were flooded with water (100 gallons daily) the distance was extended to six but not to seven feet. The lateral spread in all these cases was insignificant, amounting to not much more than a foot either way—that is, the pollution flow was steeply dome-shaped. By keeping the pit flooded with water for a prolonged period the progressive clogging effect could be demonstrated as well as the shortening of the penetration distance of the faecal organisms, the maximum penetration being observed after two months' use. It is claimed that these investigations demonstrate an important principle not heretofore developed—namely, that a pollution stream describes a path which is the resultant of the interacting forces of lineal flow with the ground water toward the discharge stream, and of variations in densities of the effluent flow in comparison with the ground water.

MALARIA THERAPY

A useful summary of the arrangements made by the Ministry of Health for malaria therapy is given in *A Report on the Provision and Distribution of Infective Material for the Practice of Malaria-Therapy in England and Wales*.¹ A scheme was initiated in 1923, and within two years the requests for infective material became so numerous that the Ministry of Health, in consultation with the Board of Control, the London County Council, and the authorities at Horton Mental Hospital, decided to establish a unit consisting of a treatment centre and a malaria laboratory at Horton. There, apart from treatment of cases and provision of material for treatment in other centres, research on malaria therapy has been steadily continued. Various strains of all the species of human malaria and also *P. knowlesi* have been investigated, but the "Madagascar" strain of *P. vivax* is usually employed for routine purposes. This strain has several advantages: it produces large numbers of gametocytes, making it easy to infect mosquitos; mosquito transmission is very certain; the incubation period of the induced

fever is relatively short (about ten to fourteen days) and shows little variation; few patients in England are resistant to infection with this strain; and the infection, although vigorous, with proper care is not unduly dangerous. Other species of *Plasmodium* are used for patients who do not develop satisfactory infections with the routine strain or have acquired immunity to *P. vivax*. The detailed descriptions of standardized procedures which have been developed for the breeding, maintenance, and infection of mosquitos will be of value to all who are working in this field. The general reader will be most interested in the arrangements that have been made for the treatment of cases outside the unit. On request, infected mosquitos are sent with a trained assistant where possible. Usually, however, infective material is supplied in the form of defibrinated infected blood, which is dispatched in small ampoules, packed in ice if the journey is likely to take more than eighteen hours. Any objection to infection by blood probably rests upon theoretical rather than practical grounds. A small record card is supplied, which the doctor in charge of the case is asked to complete and return in due course to the Ministry of Health for research analysis. Advice, if asked for, will be given during the course of treatment and blood films will be examined for parasites free of charge. The report contains a table which records the results of treating between five and seven hundred cases of general paralysis of the insane yearly since 1927. Over 50 per cent. had some favourable result, about 15 per cent. being discharged "cured" and almost 10 per cent. being discharged "improved." The conclusion is that the method at present offers one of the most satisfactory forms of therapy for sufferers from this disease, but the report does not concern itself with the mechanism of the therapeutic action or with any comparison of other methods of inducing pyrexia. The opinion is expressed that if malaria therapy is applied in a sufficiently early stage of the disease the patient will usually recover and be able to return to normal life again; but even if applied later it is found that in a large proportion of cases the expectation of life is increased, and, though institutionalized, many patients will show definite mental and physical improvement. It is to be hoped that the convenient arrangements now existing for this treatment are being fully utilized.

CAUSES OF BLINDNESS

An excellent piece of work is embodied in the thirty-second annual report of the Northern Counties Association for the Blind, a body which covers Yorkshire, Lancashire, Northumberland, Durham, Cumberland, and Westmorland in endeavouring to promote the welfare of the blind and prevent blindness. The medical subcommittee, of which Dr. Kay Sharp, consulting ophthalmic surgeon, West Riding County Council, is chairman, has analysed 10,000 cases of blindness with a view to ascertaining the causation. The classification follows the sections of forms B.D. 8 and 37 D, which are used now by all the forty-six authorities in the

¹ Reports on Public Health and Medical Subjects. No. 84. H.M. Stationery Office. Price 6d. net.

area. Of the 10,000 cases, 6,406 were found to be due to congenital or undetermined causes, primary cataract accounting for more than one-half, and primary glaucoma for one-sixth. The number of cases due to infectious and bacterial causes was 1,791, of which 405 were ascribed to ophthalmia neonatorum, and 492 to syphilis, congenital or acquired. The cases of blindness due to traumatic and chemical causes numbered 580, industrial trauma accounting for 262, and non-industrial (including 44 relics of war injury) for 286. Under "general diseases" 300 cases of blindness are listed, the largest subsection being vascular diseases, including cerebral vascular lesions, and the next largest diabetes. Of the 10,000 cases, no information as to cause was obtainable in 423. The number of females was slightly in excess of the number of males in all categories except the traumatic; in that category there were nearly four times as many males as females. The classification will form the basis of the work of the subcommittee during the coming year, when the information contained in it will be further elaborated. Another piece of work on which the subcommittee is now engaged is the production of a film for projection in schools, factories, and workshops with a view to preventing blindness.

RESPIRATION AND ANAESTHESIA

The present state of knowledge as to the regulation of respiration, with particular reference to anaesthesia, has recently been reviewed by Schmidt.¹ During normal respiration only the muscles of inspiration—namely, the diaphragm and external intercostals—are active. Their nerve centres in the medulla have the lowest threshold for chemical stimuli, and function under resting conditions, but are the most resistant to depressant drugs and other influences. Thus, in deep anaesthesia or depression due to drugs, respiratory movements may be reduced to a series of inspiratory gasps—a warning of impending respiratory failure. The Hering-Breuer reflexes from the lungs, which control inspiration and expiration, provide a factor of safety in ether anaesthesia, for the irritant action of the vapour leads to violent expiratory efforts and more complete emptying of the lungs. These efforts reflexly cause an increase in the rate and depth of respiration, which may thus be maintained at a normal level in spite of severe depression of the respiratory centre. With increasing narcosis the depth of respiration decreases, but the rate of breathing is maintained until expiratory paralysis and slowing of the rate indicate a dangerous degree of depression. The respiratory centre is also affected by other nerve impulses and by chemical stimuli, while its proper functioning depends on adequate oxygenation. It is very sensitive to changes in hydrogen ion concentration, and normally responds promptly to changes in the carbon dioxide tension of the blood—the ordinary regulator of respiration. Lack of oxygen alone acts merely as a depressant, and the stimulating effect of anoxaemia is due to afferent nerve impulses from specialized receptors in the carotid

bodies and aorta; these impulses are quite distinct from the reflexes arising in the carotid sinuses and aortic arch, which mainly control the heart rate and blood pressure. The carotid body appears to be adapted for the transformation of chemical changes in the blood into nerve impulses to the respiratory centre. These reflex impulses are more resistant than the centre itself to depressants, so respiration may be continued through the stimulus of anoxaemia although the centre fails to respond directly to the stimulus of increasing carbon dioxide. Under such conditions respiration may fail entirely when the anoxaemia is relieved by the administration of oxygen, but this risk must be taken, for continued anoxaemia implies prolonged and possibly permanent damage to the brain and heart, and it may be particularly dangerous when combined with depression caused by drugs. The hyperpnoea brought about by lobeline, cyanides, etc., appears to be due to reflexes from the carotid bodies. Though carbon dioxide is a powerful stimulant to the normal respiratory centre, it may act as a depressant when the centre is heavily narcotized, due to a direct narcotic action, or by increasing the centre's demand for oxygen when its supply is barely adequate, or, if given with oxygen, by removing an anoxaemia which was reflexly maintaining respiration. The recovery of a patient with extreme depression of breathing resulting from narcotics depends less on the administration of respiratory stimulants than on (1) removal of the drug from the brain, and (2) maintenance of oxygenation. The former is facilitated by improving the cerebral circulation, by transfusion, etc., and also by lowering the cerebrospinal fluid pressure by the intravenous infusion of hypertonic sucrose (50 per cent.) solution; glucose or saline infusions may increase the cerebrospinal fluid pressure. The value of the usual stimulants—strychnine, caffeine, camphor, coramine, picrotoxin, etc.—is questionable, for they have little effect on the severely depressed centre. Lobeline is probably the best stimulant, but its action is transitory and may be followed by depression; it is not indicated when the breathing is weak or absent in the presence of severe cyanosis, for the cyanosis shows that the centre is too depressed for reflexes from the carotid body to be effective. The increasing incidence of asphyxia neonatorum in recent years is probably due to the greater use of non-volatile narcotics during labour. The foetal brain is normally in a state of anoxaemia, and is thus unduly sensitive to depressants; where possible volatile agents which are rapidly excreted should be used. Asphyxia is best treated by insufflation of oxygen by means of a tracheal tube; carbon dioxide should be added not for its stimulant effect but to prevent undue depletion of its tension in the blood.

The Semon Lecture, entitled "Laryngology's Debt to Research," will be given by Mr. W. M. Mollison at the Royal Society of Medicine, 1, Wimpole Street, W., on Thursday, November 3, at 5 p.m. The lecture is under the auspices of the University of London, and the chair will be taken by Mr. C. A. Scott Ridout, president of the laryngological section of the Society.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

INFECTIONS OF THE HAND AND FINGERS—III

BY

NORMAN C. LAKE, D.Sc., M.D., M.S., F.R.C.S.

Incisions

Infection of the pulp of a finger is best dealt with by an incision that skirts the end of the finger about one-eighth of an inch from the nail margin, which it follows. The whole pulp is raised as a flap from off the periosteum of the underlying bone (Fig 6, *a*). The wound is kept wide open by packing the interval with gauze soaked in a suitable antiseptic, such as 1 in 1,000 flavine. In this way all the loculi previously described are drained, as this incision cuts across the bases of them all. The spread of infection is thus arrested, and the bone, unless already involved, is saved. When the infection has been overcome the flap falls back readily into position with an intact

FIG. 6.—Incisions for drainage of infections of terminal phalanx. (*a*) Incision for draining pulp. (*b*) Flap turned back. (*c*) Flap to be turned back for drainage of infection of the root of the nail. (*d*) Transfixion incision for drainage of central pulp infection.

nerve and blood supply; the final sear is obviously well removed from all pressure points. In some cases half only of the flap is raised: this is especially useful when one side of the nail groove is involved. Exceptionally, a central infection of the pulp may be treated by a transfixion incision extending from one side to the other (Fig. 6, *d*).

Infections under the nail are best dealt with by removal of that structure, either wholly or in part. For central infections of the nail bed it is sometimes recommended that a small trephine hole be made through the underlying nail, but this is apt to provide very inadequate drainage, and in the long run little time is saved over the more certain removal of half or the whole nail. When the root of the nail is involved, as in onychia, two lateral vertical incisions are made, continuing the line of the

lateral nail groove for about half an inch (Fig. 6, *c*). The whole skin flap thus outlined is raised off the nail root and packed as above. Multiple chronic infections of the nail groove are not uncommon. In some cases there may be a general syphilitic or tuberculous infection; in others, infection is due to a ringworm; but in a third variety, of increasing frequency, manicuring is to blame. For this group in the earlier stages local antiseptic applications, especially those having great penetrating powers, are advisable. Ultra-violet light has also proved effective in many instances, but for those intractable cases where,

FIG. 7.—Diagram indicating position of incisions for drainage: (*a*) of digital thecae, (*b*) of proximal end of digital thecae, (*c*) of ulnar bursa, (*d*) of theca of thumb.

owing to reinfection or lack of resistance, the condition fails to respond to other methods, removal of all the nails may prove the quickest method of clearing up the infection.

Infections in the intermediate and proximal sections of a digit are drained by lateral incisions which avoid the nerves and vessels by keeping well on to the palmar aspect. These incisions into the subcutaneous tissues may cross the skin creases with impunity. Drainage of the thecae is a much more difficult problem. If the whole length of a theca were to be opened by a median incision an adequate drainage would undoubtedly be established, but the tendons would retract out of the wound like a "bow-string." It is true that this might be avoided by splinting in complete extension, but dense anterior adhesions would form which it would be impossible to break down subsequently. In addition the sheath would

be weakened at its most important part and the sear would be right over the pressure area. For these various reasons the incisions are usually made in a bridged fashion (Fig. 7, *a*) leaving the intervening portion of the theca intact. They are placed at the lateral borders of the sheath, but carefully avoid the digital nerves and vessels. With these provisos the incisions should be made as extensive as possible.

The extension of a theca into the palm may be drained by a median incision (Fig. 7, *b*): care is necessary, however, in the case of the index finger to avoid the nerves and vessels which cross it (see anatomical section, Fig. 3).

There is some divergence of opinion as to the best position into which to fix a finger in these cases. If

approached directly through the palm without grave risks of damage to important structures. The routes by which these infections spread naturally have already been outlined, and it is along this same track that the surgeon should attempt their drainage. The incisions are therefore made in the appropriate web spaces, and, from these, sinus forceps are carefully pushed into the deep spaces until pus is reached. The operator must visualize the position of these spaces in so doing. Drainage may be maintained by keeping the tracks open with strips of thin glove rubber. No drainage tube should be used owing to the great risk of causing pressure necrosis and secondary haemorrhage. In view of what has already been said on this subject in previous paragraphs there should be no

FIG. 8.—Diagram of the important structures in the palm. (a) Ulnar nerve. (b) Ulnar artery. (c) Superficial palmar arch. (d) Deep palmar arch. (e) Median nerve.

the theca is not divided in its whole length there is little fear of tendon prolapse, and a somewhat flexed finger is much easier to manipulate than one which is fully extended, so that any subsequent adhesions can be more easily dealt with. Difficulties may arise when it has been impossible to say before operation whether the theca is involved. In these circumstances the surgeon should first dissect carefully down to the theca. If it is obviously infected it can then be opened; if it is doubtful the wound may be left wide open and a fresh observation made in twenty-four hours. In exceptional cases the discreet use of a needle and syringe may decide the issue, but the greatest care should be taken not to introduce infection in so doing.

Drainage of the Palm

A glance at the anatomical diagrams (Figs. 8 and 9) will indicate that infections in the palmar spaces could not be

FIG. 9.—Transparency showing the relation of the palmar and thenar spaces of Kanavel to the chief overlying structures. The horizontal lines represent the limits of the anterior annular ligament.

need to warn the unwary against making incisions into the swollen tissues on the dorsum of the hand.

The proper drainage of the theca of the thumb and of the main palmar bursa demands a rather high degree of skill, otherwise considerable damage may be done to the important structures which are crowded together in this region. These thecae may be approached through the lateral and medial extensions of the palmar fascia, which are much thinner and less important than the central portion. Before dealing with these cases the operator should review the anatomical diagrams (Figs. 4 and 9). The incision for drainage of the thumb theca skirts the inner margin of the thenar eminence. The sheath is first opened in its distal portion, where it is easy to find, and is then followed upwards towards the wrist. Part of the vascular and sensory nervous supply to the thumb crosses the sheath, and should if possible be

preserved. In any case the incision must not extend so far proximally as to endanger the motor nerve supply of the thenar muscles from the median. The proximal end of this bursa may, however, be drained in the forearm immediately above the annular ligaments (Fig. 7, *d*).

The common palmar bursa and its extension to the little finger is drained by an incision which follows the ulnar border of the sheath. Part of the sensory nerve supply of this digit crosses the sheath and may perforce have to be sacrificed. The incision must be strictly limited proximally to avoid damage to the ulnar nerve, but the proximal end of this bursa may be drained in the forearm, as in the case of the thumb (Fig. 7, *c*). The deep space of the forearm, which may become infected by extension from the palmar space and which lies deep to the tendons and their bursae, is drained by medial and lateral incisions which approach the space from both aspects; the superficial structures are retracted forwards.

Involvement of bones will be very largely avoided if early and adequate drainage of more superficial infections is instituted. Bone infection, especially of the terminal phalanx, may be suspected if the wound or sinus does not readily close, if the finger remains swollen, or if fresh abscesses and sinuses form. The use of a probe will reveal a necrotic bone, and in these cases, although not in the initial stages of bone involvement, a radiograph is of great value. At the earliest possible moment the cavity should be laid freely open and all necrotic bone removed. It has already been mentioned that the terminal joint and the tendon sheaths usually escape. The final result following necrosis of the terminal phalanx, when the soft tissues have not been allowed to become extensively destroyed, is good.

Necrosis of the long flexor tendons is a serious outcome of infection. This sequel could be very largely avoided by the early recognition and energetic treatment of infections by operation. Efficient drainage of a sheath as soon as it becomes infected, followed by splinting of the digit, allows adhesions to form between the tendon and the sheath, which limit the further spread of the process. These adhesions are usually thin, and can be easily broken down subsequently. For the reasons already given, if the sheath be not drained early the tendon will surely undergo necrosis and the function of the finger be thus destroyed. A dead tendon must be removed, since it is otherwise a source of prolonged suppuration, and there is nothing to be gained by its retention. At a later date the question of a plastic operation or of amputation of the digit will have to be considered.

Infection of joints is luckily uncommon, at least until the general condition of the digit has become so serious that there is little hope of retaining it. In the rare examples of solitary joint infection the condition is recognized by the localization of the swelling and the immobility of the joint concerned. As in the case of joint infections elsewhere, incisions are made down to and through the capsule, but no drainage material is allowed to enter the joint cavity.

It remains to consider the value of hot baths, Bier's congestive bandages, etc., in the treatment of these cases. Many have great faith in the value of hot arm baths with various antiseptics, and in cases where adequate drainage has already been established there may be some virtue in the method. Frequently, however, the use of these measures leads to procrastination in dealing with the spread of infections by surgery, and in these circumstances they are to be condemned. Hot baths, etc., must never be allowed to replace surgical drainage; but there

may be little harm, and possibly equally little value, in using them after such drainage is established. Occasionally, if the edges of an incision tend to become encrusted with discharge which prevents free drainage, a bath of weak flavine, eusol, or milton may be used, but it should be repeated with caution lest the skin become sodden.

The application of a Bier's congestive bandage appears at times to be of some value, but it must not be expected to replace surgical measures. It may be used both in the very early stages to help localization, and later, after drainage, to flush the wound with serum and assist free discharge.

The treatment of the chronic infections previously mentioned falls outside the scope of this article.

Prophylaxis

Finally a word must be said concerning prophylaxis. It has been pointed out that many of these cases arise from wounds and injuries, so that, except for certain difficulties already considered, it would appear feasible to prevent the complication of infection in a large number of them. In the hand, with its anatomical complexity and the contraction and retraction of structures after division, immediate complete sterilization of the wound will very often prove impossible. It is therefore frequently an error to attempt immediate closure. The wound should be left wide open, after a preliminary cleansing, and packed lightly with some suitable antiseptic gauze. After a few days a secondary suture may be attempted without fear of gross infection. Divided structures of importance may have an identifying suture passed through them, to prevent retraction and to aid recognition at the secondary suture. Punctured wounds—for example, those produced by needles—present a special problem in prophylaxis. If the penetration is known to be of very limited extent, it may be proper to attempt sterilization by the passage, along the track, of the eye end of a needle dipped in carbolic. In most cases, however, it is wise to avoid the use of strong antiseptics and to rely upon suction or the use of a congestive bandage above the part for twenty-four hours or so.

LISTER AT UNIVERSITY COLLEGE AND HOSPITAL

ADDRESS BY SIR SICLAIR THOMSON

At a reception held at University College Hospital on October 11 Sir StClair Thomson, who was house-surgeon to Lister in 1883, delivered an address on Lister at University College and Hospital.

Sir StClair said that University and King's Colleges had only recently celebrated their first centenary and both could rejoice in cherishing the memory and example of the greatest of all the masters of surgery, for Lister felt the first impulse towards his great life-work in University College Hospital, and this reached its fruition during the sixteen years that he worked in the wards of King's College Hospital to demonstrate the truth of his principles. Lister was a "true-born Englishman." His people came from Yorkshire. His father was a wine-merchant in the City of London, and had a love of learning and a taste for scientific pursuits, for he was deeply interested in the science of optics, helped to perfect the microscope, and was a Fellow of the Royal Society. He was also a good classical scholar and skilful both with his brush and pencil. Moreover he was a Quaker, and Joseph Lister grew up in the atmosphere of that rather serious-minded sect.

R. BODLEY SCOTT: THE SARCOIDOSIS OF BOECK

FIG. 1.—Case V. Radiograph of chest showing enlargement of mediastinal and hilar lymph-nodes.

FIG. 2.—Case VI. Radiograph of chest showing enlargement of hilar lymph-nodes with the miliary type of sarcoid lesion.

FIG. 3.—Case I. Radiograph of chest showing diffuse pulmonary fibrosis.

FIG. 4.—Case VIII. Radiograph of hands. Changes of osteitis multiplex are seen at distal end of proximal phalanges of left thumb and third finger and right third finger.

FIG. 5.—Case IV. Photomicrograph of lymph-node showing changes of sarcoidosis.

J. B. McDOUGALL AND J. H. CRAWFORD: TOMOGRAPHY IN PULMONARY TUBERCULOSIS

FIG. 1A.—Ordinary radiograph of chest of Case I. Lesion fibrotic and bilateral.

FIG. 1B.—Tomogram of Case I taken at level of 5 cm. from back of chest.

FIG. 2A.—Ordinary radiograph of chest of Case II.

FIG. 2B.—Tomogram of Case II taken 5 cm. from back of chest. Large cavity in right lower lobe now obvious.

J. B. McDOUGALL AND J. H. CRAWFORD: TOMOGRAPHY IN PULMONARY TUBERCULOSIS

FIG. 3A.—Ordinary radiograph of Case III taken in the erect position.

FIG. 3B.—Lateral tomogram of the left lung of Case III taken in the plane of the mid-clavicular line.

FIG. 4A.—Ordinary radiograph of Case IV.

FIG. 4B.—Median tomogram of Case IV, taken midway between front and back of chest.

G. H. JENNINGS AND J. G. GLAZEBROOK: CLINICAL AND BLOOD PICTURES IN ADULT SCURVY

FIG. 1.—Case I. Adult scurvy, showing extensive extravasation of blood in right popliteal fossa and posterior part of thigh.

FIG. 2.—Case I. Extravasation of blood around right ankle and on right shin. Some oedema of foot.

FIG. 3.—Case I. Showing swelling of left knee with peri-articular and popliteal extravasations marked by tight bandage. Petechiae into hair follicles.

FIG. 4.—Case II. Forearm with bleb-like extravasations of blood resulting from slight traumata a year previously. Result of a recent tourniquet test also seen.

FIGS. 5 and 6.—Case II. Gums of upper and lower jaw showing considerable swelling and discoloration.

Lister's Student Days

Being debarred from Cambridge and Oxford, Lister entered University College in the spring of 1844 at the age of 17. The College had been founded recently as a non-sectarian institution, just as King's College was started a few years later to maintain the tenets of the Church of England. Lister, a Quaker, began his long life of study in the one college and finished it in the other, having on his marriage at the age of 29 joined the Church of England. He bequeathed £10,000 to King's College Hospital and exactly the same amount to University College Hospital—nearly one-third of his fortune. The remainder of his fortune—not a large one—was all, except a small amount, left for public use.

Three years were passed at the College in taking the degree of B.A. Apparently these were not the happiest of his life. During this period Lister was described by a junior fellow-student as "rather dwelling apart and not making any strong fellowship with his fellows." He had an attack of small-pox, returned too soon afterwards to his studies, and then had a serious nervous breakdown which necessitated a long holiday.

Lister was 20 years of age when he entered the medical department in 1848, and was fortunate in coming under the care of such eminent teachers as Lindley, teacher of botany; W. B. Carpenter, of medical jurisprudence; Graham, of chemistry; and Ellis, of anatomy. Another well-known teacher was Wharton Jones, who, although ophthalmic surgeon at the hospital, was better known as a philosopher and a man of wide culture.

Lister took his M.B. in 1852, and not only obtained distinction in other subjects but carried off the gold medal and scholarship in surgery. In 1852 he obtained the F.R.C.S., having already served as house-physician to Dr. Walsh and house-surgeon to Sir John Erichsen. It was not necessary in those days to be qualified before holding a resident appointment. He was thus, Sir StClair continued, 25 years old when he finished his long student-ship and close association of no less than nine years (1844-53) with your great school. In his student days Lister was an active member of the debating society and an energetic supporter of the hospital medical school. The direction of his thoughts, even in these student days, towards science and towards the cause of sepsis was shown by his reading a paper on the use of the microscope and one on hospital gangrene.

"First Operation with Anaesthesia"

The first operation ever carried out in this country under a general anaesthetic was performed in University College on December 21, 1846, not a hundred years ago, and Lister was present at it. It was performed by that brilliant operator Liston, who, to spare the patient pain in those pre-anaesthetic days, had acquired such dexterity that it was recorded that he could amputate a limb in less than half a minute. In the picture (which Sir StClair demonstrated) recording this historical occasion they would see that the ether was being administered by Mr. Squire, of the old-established firm of chemists which flourishes in Oxford Street. Liston was being assisted by W. Cadge, who afterwards was a well-known surgeon in Norwich and throughout East Anglia. Next to him was another distinguished pupil of this school, Russell Reynolds, who became President of the Royal College of Physicians. The next but one on his right was Lister, who at the time was house-surgeon to Erichsen, represented sitting down beside him. Among other U.C.H. men in the picture were Graily Hewett, afterwards a well-known obstetrician on the staff, and Clover, who became one of the early anaesthetists and was still remembered by Clover's inhaler. The operation was an amputation through the thigh. Its duration was timed by Squire and three of his assistants, and their records varied between 28 and 25 seconds.*

Lister not only resided in the hospital as house-physician and as house-surgeon, but in the latter office he served an extra half-term. His intense conscientiousness impelled him to devote still more time to perfecting his knowledge and experience by a tour of some foreign schools before embarking on practice. Sharpey, the professor who had done so much in fostering Lister's physiological bent, advised him, before visiting Continental schools, to go to Edinburgh to work under Professor James Syme, then one of the leading surgeons of Europe. In Edinburgh Lister became Syme's house-surgeon, then his assistant, then his son-in-law, and finally succeeded him as professor of surgery in the University.

Lister, Sir StClair remarked, had done more for the progress of surgery than all the surgeons of the world since the days of Hippocrates had together been able to effect. The application of his principles, even during his lifetime, saved more lives than all the wars of Napoleon had destroyed. It was his work which had made possible most of the achievements of surgery and of medicine in this age.

Septic Surgery

Those who were not living in the time of this astounding evolution might feel some difficulty in realizing with what horrors surgery was accompanied before his day. Suppuration occurred in the majority of operation wounds; every surgical ward in the world reeked with the stench of putrefaction; and the "hospital smell" in surgical wards was accepted as inevitable. The operation death rate before the coming of Lister—and even in his own wards in early days—was from 25 to 40 per cent. In 1874 Erichsen published the results of all the amputations in University College Hospital and recorded that he considered a general mortality of 25 per cent. "a very satisfactory result." Sometimes in military hospitals the death rate would mount up to 75 to 90 per cent. In lying-in hospitals the death rate might at times reach a mortality of 25 to 35 per cent. Last year, in this country, it was not 30 per cent. but about 30 per ten thousand. When Lister worked in their wards the scope of surgery was so limited that one theatre and one day a week were sufficient for the operations of the entire staff. The operations consisted chiefly of amputations of limbs crushed by accidents, or with compound fractures, for in those days, as in all our wars up to the Boer War at the end of last century, compound fractures were so generally followed by sepsis, pyaemia, and death that amputation was the usual treatment. Operations were rarely if ever attempted on the cavities or joints of the body, and no one in those days could even imagine the miracles which were awaiting the coming of Pasteur and Lister. Erichsen, to whom Lister was house-surgeon, was even rash enough to prophesy in 1874 that "the abdomen, the chest, and the brain would be for ever shut from the intrusion of the wise and humane surgeon." Another surgeon had pronounced that "an abdominal operation should be classed amongst the methods of the executioner."

University College Hospital was perhaps the first in London to learn of Lister's evangel and to practise his methods. Marcus Beck, a brilliant man on the junior staff and one whose early death was universally deplored, was a cousin of Lister, with whom he lived and studied in Glasgow. In 1876 he was one of the first to carry out antiseptic methods thoroughly and efficiently. This was done in face of such almost unbelievable opposition that he wrote to his relative that "it is a very thankless task to preach antiseptics to a London audience." Later on University College Hospital supplied another apostle who met with more success—namely, Sir Rickman Godlee, a nephew of Lister.

Lister, Sir StClair Thomson said in conclusion, had wrought more for the relief of bodily suffering, for the security of human life, for the prevention of anxiety, for the conversion of fear into joy, for the promotion of happiness, and for the enrichment of the life of mankind than any one man who had ever trod this earth.

SOUTH AFRICAN MEDICAL CONGRESS

PROCEEDINGS AT LOURENÇO MARQUES

The thirty-second South African Medical Congress, the first in Mozambique Colony, was held in Lourenço Marques from September 8 to 14 under the presidency of Dr. Vaseo Palmeirim, Director of Medical Services of the Colony of Mozambique. The programme, as in previous South African Congresses, included plenary sessions, sectional meetings, annual meetings of groups of the Medical Association of South Africa (British Medical Association), and entertainments. Congress met in plenary session during the first half of four mornings. On Friday, September 9, there was a symposium on broneho-pulmonary non-tuberculous suppurations. The subject was introduced by Dr. N. de Almeida of the Instituto Português de Oncologia, Lisbon; and from the radiological aspect by Dr. R. J. W. Charlton of Johannesburg. The openers of the discussion were: from the medical aspect, Dr. D. P. Marais of Capetown; from the surgical aspect, Mr. A. Radford of Durban; and from the radiological aspect, Dr. S. Ferreira of Lourenço Marques. Saturday morning was devoted to a symposium on malaria, a subject of very great local interest. Papers were contributed by Drs. Alberto Soeiro and A. Rebelo of Lourenço Marques on the epidemiology and parasitology of the disease; by Professor Froilano de Melo of Nova Gôa (Portuguese India) on treatment; and by Dr. A. J. Ornstein of Johannesburg on the drug prophylaxis of malaria. The openers of the discussion were Drs. A. Pijper of Pretoria, J. A. Maefadyen of Durban, and M. Andrade of Lourenço Marques.

Anti-malaria Campaign in Tropical Africa

Dr. Alberto Soeiro, who is physician at the Central Hospital at Lourenço Marques, in his paper on some aspects of the anti-malaria campaign in tropical Africa, pointed out that it would not be far from the truth to affirm that malaria affected one-third of the population of the world. It had rendered difficult and sometimes impossible the agricultural and industrial development of some of the richest regions. About 2,000,000 lives paid an annual toll to malaria. This number did not include the lives lost indirectly by the pauperization which malaria provoked in various populations. In tropical Africa the fight presented many complicated problems, generally intimately associated with climatic and topographical conditions, or with the primitive conditions under which the inhabitants lived and with the scarcity of population.

Malaria control was always an essentially local problem, and therefore there were as many different methods of fighting it as there were infected regions. Experience proved that it was impossible to employ exclusively one method without losing sight of the economic factor, which must always be borne in mind at each step. The great difficulty was due partly to the prodigious fecundity of the anopheles and its facility of adaptation, which was aggravated, in tropical regions, by climatic conditions eminently suitable for its multiplication, and partly to the ignorance and indifference of the native populations. The work of the entomologist was as necessary to the doctor as the competency of the doctor was indispensable to the entomologist. In the task of malaria control it was necessary to bear in mind, first, that any method employed must be accompanied by constant vigilance and rigorous continuity; secondly, that no campaign could be undertaken without secure financial means which allowed the realization of a previously studied plan; and, thirdly, that the initiative must be taken by the State and municipalities, which must start works of sanitation and encourage others to do so on all lands that might constitute a danger to public health. Many problems still

needed to be studied, notably the influence of malaria on native infantile mortality, the influence of treatment on the immunity of native populations, the various strains of parasites, the local standard treatment, and the prophylaxis of malaria in Africa.

Angiopneumography

On Monday gastric and duodenal ulcers were discussed. Their treatment was dealt with in papers by Dr. V. Palmeirim of Lourenço Marques and Mr. Lindsay Sandes of Capetown; radiological aspects were discussed by Dr. S. Ferreira of Lourenço Marques and Dr. M. Weinbren of Johannesburg. Set down for the same morning was a discussion on the importance of angiopneumography for the interpretation of pulmonary radiographs. This subject was presented by Professor Lopo de Carvalho. He stated that after numerous experiments on laboratory animals he had succeeded with his collaborators, in May, 1930, in visualizing the pulmonary vessels in man. The solution of the problem might seem quite simple, since the methods of cerebral arteriography introduced by Egas Moniz and those of abdominal aortography carried out by Reinaldo dos Santos were both based upon the injection of an opaque substance into the blood stream. Such was not, however, the case. Long and wearisome experiments had to be carried out in order to render angiopneumography practical and harmless. The essential of this new method consists in injecting into the right auricle of the heart a highly concentrated (120 per cent.) solution of sodium iodide. The auricle is reached by means of a catheter opaque to x rays introduced into one of the cubital veins, its gradual advance being followed on the screen. The catheter is pushed in slowly and, simultaneously with its introduction, small quantities of physiological serum are injected with the aid of a syringe fitted to the other end of the catheter. This makes its progress easier and prevents the formation of blood clots within the tube. As soon as the auricle is reached, or the lower end of the vena cava, the x-ray apparatus is made ready for taking the photograph and the cassette with the film is placed against the patient's thorax.

This new method was as yet in its infancy, but the results obtained were so precise and clear as to allow the assumption that it would be possible in the near future to solve some of the problems of the semiotics and pathology of pulmonary diseases that were at present still obscure. He remarked that timorous people might still be afraid of the application of the angiopneumographic method. Its harmlessness, however, had been sufficiently clearly demonstrated to justify the widest possible application. The discussion on this subject was opened by Dr. S. K. Montgomery of Capetown.

At the final plenary session two subjects were considered. Professor C. F. M. Saint of Capetown introduced a discussion on the toxæmia of thyroid diseases, while that on the circulation of the myocardium was introduced by Professor Maximino Correia of the University of Coimbra.

Work in the Sections

The remaining papers were distributed among the usual five sections: medicine, surgery, gynaecology and obstetrics, public health, and special subjects. A large number of papers on a great variety of subjects were read and discussed. Many of these were, as was to be expected, on subjects of local interest. They included such subjects as African ethnology by Dr. R. Elsdon-Dew of Johannesburg; artificial feeding of infants in the Tropics by Dr. F. Martins of Lourenço Marques; malignant tumours of the liver in Mozambique natives by Dr. M. D. Prates of Lisbon; and surgical tuberculosis among non-Europeans by Dr. G. T. du Toit of Johannesburg. Malaria came in for further discussion in the section of public health, where Dr. Botha de Meillon of the South African Institute

for Medical Research contributed a valuable paper on the researches he has for several years been carrying out on local anopheles. An interesting paper in the section of medicine was that of Professor Grober of the Jena Institute for Physical Therapeutics, which dealt with the acclimatization of Europeans in South Africa. Professor Grober's departure from Germany had unfortunately been delayed by illness. In his absence his paper was read by Miss Riemerschmid, who during the previous eighteen months had been carrying out a solar survey of the Union of South Africa under the auspices of the Jena Institute. The paper discussed the data so far collected by Miss Riemerschmid.

The significance of wild animals as carriers or reservoirs of disease to the stock-raising industry of the Union was dealt with in a paper read by Dr. Gilles de Kock, Acting Director of Veterinary Services of the Union of South Africa Agricultural Department. With regard to the outbreak of foot-and-mouth disease which occurred recently in the Game Reserve at the Kruger National Park, he said, the question had been raised whether the disease was enzootic in game. He described the outbreak, which was diagnosed on July 20 in a herd of cattle by one of the rangers, and said that though infection in cattle was probably not associated with that in game the possibility had not been overlooked. Dr. de Kock also said that small herds of cattle would be maintained in the Kruger National Park to serve as a "barometer" to indicate whether domesticated animals would become infected from game. All officials concerned with the control of game had been instructed to keep a very sharp lookout for anything of a suspicious nature among game. Suspected animals would be shot and examined. Active steps had also been taken to eliminate every possible source of infection from outside. It was hoped that by this means information would be gained as to whether foot-and-mouth disease was enzootic in game in the Kruger Park. Should that be the case the Union authorities would attempt isolation of the Game Reserve in such a way that it would not endanger stock in the rest of the Union.

Malnutrition

The public conscience in the Union has recently been greatly stirred by the accumulating evidence of undernourishment among the Bantu (negro) and "poor white" populations. The subject was hotly discussed in Parliament during the budget debate in August. As two papers were set down on the programme for combined discussion by the sections of medicine and public health a lively discussion inevitably ensued. The debate demonstrated that the medical profession in South Africa was only too well aware of the extent to which the health of a large portion of the population was being undermined by the grossly inadequate amount of protective foods being consumed in the country. No fewer than seven resolutions with various amendments were tabled during the discussion. Some of these savoured too much of dictation to the Government, and were reluctantly withdrawn. Eventually a comprehensive resolution, proposed by Dr. Gilles de Kock, Deputy Director of Veterinary Services for the Union, and seconded by Sir Edward Thornton, former Secretary for Public Health of the Union, was carried unanimously. This resolution read as follows:

"That in view of the extent of malnutrition or undernourishment in South Africa and the deleterious effects on large sections of the population this Congress recommends: (1) that every facility be given by the departments concerned to expedite the investigations into the human, animal, agricultural, and economic aspects of nutrition, so that it can be placed on a proper basis; (2) that the closest contact between the research departments concerned with the problem be established; and (3) that measures be immediately considered by the departments concerned to deal with the existing

position, particularly in respect of the children in badly affected areas."

A further resolution was also passed recommending to the Union Government the advisability of buying maize at current prices for storage and its subsequent distribution at cost price plus storage to natives in the rural areas during the winter and spring seasons. Other motions urged the extension of the subsidized milk and butter schemes, and that the issue of subsidized milk be extended to the native population.

Aircraft and Yellow Fever

The risk of aeroplanes spreading yellow fever throughout the continent of Africa was emphasized by Dr. G. A. Park Ross, Deputy Chief Health Officer of the Union, in an address to the public health section. He declared that the consequences to trade of infection down the East Coast would be appalling. He had devised apparatus which would automatically "disinsect" aeroplanes: Imperial Airways had equipped one of its machines with this apparatus for experimental purposes. He urged that the cleaning of aeroplanes should be made compulsory. The classical urban type of yellow fever carried by *Aedes aegypti*, he said, was widely distributed in West Africa, and might already be found east of the Nile. It had not been demonstrated in Uganda or Kenya, or in territories to the south. In the vast Congo Free State its distribution was so far undetermined. Jungle yellow fever, an identical disease carried by a different vector, had not so far been demonstrated in Africa. Not nearly enough sampling of populations, human and monkey, by the mouse-protection test had been done, especially south of the Equator. Sampling, however, was now proceeding apace under the Rockefeller Institute at Entebbe; until a definite absence of infection in man and monkey was proved there was no alternative but to regard certain large portions of the continent as potentially infective. Were infection introduced, say, to the East Coast, it might exist for a long time without being recognized; it might establish itself as the urban or the jungle type or both—in which case it would probably not be eradicable.

Plane-carried infected passengers and mosquitos were the danger. The former were infectious in the incubation stage, and might be carriers for six days before the disease manifested itself. In six days one could travel anywhere across the continent by air. Under African conditions of air travel the infected mosquito was a far graver risk. Present arrangements to prevent conveyance of vectors were cumbersome and not trustworthy. Regulations governing traffic presumed that planes could be relied on to land only at scheduled aerodromes, that these scheduled aerodromes were kept mosquito-free, and, lastly, that local arrangements on aerodromes dealt effectively with plane-carried mosquitos. He demonstrated the apparatus and special disinfectant he had introduced, and discussed their application to planes, giving details of the arrangements for handling passengers and suspects at Durban, where, by combining examining offices and detention and hospital quarters on a floating unit instead of on shore buildings, he claimed to have solved the mosquito and detention question not only satisfactorily but more cheaply than at any other port. The discussion which followed indicated that medical men in South Africa refused to be unduly alarmed at the suggested risk of introduction of yellow fever infection into the country. It was generally conceded, however, that the position warranted careful watching by the authorities.

Entertainments

The Portuguese hosts were lavish in their provision of entertainment of all kinds to delegates and their wives. All the sports and other clubs conferred honorary membership upon the visitors. The official programme of enter-

tainments included the presidential reception at the famous Polana Hotel on Thursday evening; a garden party held on Friday afternoon in the grounds of the Governor-General's residence, which was attended by about 800 guests; a play entitled *Dr. Knock; or, the Miracle of Medicine* by Jules Romains (translated from the French) performed at the Gilviente Theatre by local amateurs, headed by Dr. Abel de Carvalho, secretary of the Congress; an open-air fête in the Polana Hotel Gardens on Saturday night; and on Sunday afternoon a native fête was witnessed, and that evening a nautical fête in the harbour. Dr. Vasco Palmeirim presided at the Congress banquet on Monday night. Mr. Lindsay Sandes, replying to the toast of the Medical Association of South Africa, congratulated the Portuguese doctors on the high standard of their papers read at the conference. On behalf of the South African Branch of the British Medical Association, he presented Dr. Abel de Carvalho, honorary organizing secretary of the Congress, with a suitably inscribed gold watch. Sir Edward Thornton said two outstanding impressions had been gained from the visit. They were the high standard of medical service in Mozambique and the warm comradeship with fellow-workers in South Africa. Dr. Abel Gouveia Pinlo proposed the toast of the guests, and Professor Dart of the Witwatersrand University replied, concluding his speech in Portuguese. The social side of Congress was concluded on Tuesday night by a very successful ball.

COMMONWEALTH FUND FELLOWSHIPS

The Commonwealth Fund of New York has established for British subjects a number of fellowships tenable at American universities, not more than five of which will be offered in 1939 to persons holding appointments over-seas under the British Government, the Government of India, or the Government of a British Dominion, Colony, Protectorate, or Mandated Territory. The actual number of service fellows to be appointed in 1939 will be determined by the Committee of Award.

Candidates must be of British descent, single or married, and must not have attained the age of 35 on September 1 of the year of award. They must submit a definite scheme of research work or advanced study to be carried out during their residence in the United States, and must produce evidence of their capacity to pursue it with advantage; but, speaking generally, no limitation is imposed on the subject of study to be undertaken. Fellowships are tenable for a minimum period of fifteen months and a maximum period of twenty-four months, which will run from the date of departure from the country in which the fellow is engaged in Government service to the date of his arrival on return. There is no fixed stipend, but it is estimated that the cost to the Commonwealth Fund of each fellowship is approximately 3,000 dollars per annum. Each fellowship includes provision for: (a) An equipment allowance of 200 dollars and the cost of the fellow's travel, but not his wife's, from the country in which he is serving to the United States and return. (b) Tuition, laboratory fees, etc. (c) 150 dollars a month, paid quarterly, for living expenses during the tenure of the fellowship, from the date of leaving the country in which the fellow is serving. An advance of one month's living allowance may be made to an appointee. (d) Allowance for travelling while in the United States on tours approved by the Commonwealth Fund. An additional allowance at the rate of 50 dollars a month, with some increased provision for summer travel in the United States, is made for a married fellow accompanied by his wife, but he is not at liberty to bring his children to the United States except by special permission of the Fund. The Committee hopes to notify successful candidates before the end of April, 1939, and applications, submitted on the prescribed form, must reach the Secretary, Commonwealth Fund Fellowships, 35, Portman Square, W.1, not later than February 1, 1939.

OPENING OF THE NEW SESSION LONDON SCHOOL OF MEDICINE FOR WOMEN

LORD HORDER'S ADDRESS

At the opening of the new session of the London (Royal Free Hospital) School of Medicine for Women an address was delivered by Lord Horder on the aptitude of women for clinical medicine. The Dean of the School, Dr. Elizabeth Bolton, presided.

Lord Horder said that there was nothing more natural than that women should take up the profession of medicine and succeed in it. Was there so much difference between doctoring and nursing? And would anybody suggest that women's success in nursing was a matter for surprise or even for congratulation? Between the man doctor and the woman doctor there was no essential difference, though he thought that a good man doctor had a little more of the feminine in him than the average, and a similar sentiment applied to the woman doctor. He believed it to be the fact also that the proportion of charlatans among women was much smaller than among men. Women were said to have more intuition than men, and there were those who thought that this should give them an advantage over their male colleagues in the direction of what was sometimes called clinical instinct. Certainly women were more thorough than the opposite sex—a part, he supposed, of their greater conscientiousness—while, on the other hand, men displayed more initiative. Again, women were more curious than men, a curiosity which had borne fruit in those women who had already made their names famous in research.

That women were more industrious and more studious, he was, with shame, compelled to admit, though he warned them against vaunting themselves overmuch with regard to this virtue. If indulged in to excess it might, like any other virtue, be their undoing. Seriously, he warned them also against too much study and reading. If they read too much they would find that they had not left themselves time to think and to do essential things. Knowledge was valuable in so far as it helped one in action. Medicine demanded of its students of either sex a whole-hearted devotion and the fullest employment of all the faculties they possessed.

Powers of Observation

The power of observation, Lord Horder went on, was one particularly to be cultivated by the doctor, man or woman. All the faculties might be brought into action in the endeavour to observe—the sight, the hearing, and the smell could all be employed to note the deviations from the average so that deductions might be drawn. Observations of the characteristics of average people, their facial colour, how they shook hands, how they carried on normal conversation, how they breathed, all helped to train the mind to use instruments with greater efficiency when it came to the consulting-room. The sound of a cough and the rhythm of breathing, even over the telephone, were full of meaning to the trained ear. Clinical instinct was not a sixth sense; it came from the fact that some people trained their powers of observation until they observed without being conscious of doing so.

A diagnosis should never be made on negative findings. If nothing wrong could be found the whole subject should be reviewed again in the light of the simple deviations from the average that had been noticed. Each might be small, but, taken together, they formed a basis for diagnosis. Books and instrumental technique could never supply that knowledge and fundamental wisdom which medicine demanded. Industry could never be a substitute for sensitivity, and therefore medicine wanted the woman in the doctor just as much as it wanted the doctor in the woman.

Finally Lord Horder indicated the wide fields open to the woman doctor. She must be tired of hearing references to her special fitness for obstetrics and school inspection. Every field was open to her. In the sociological field there was great room. He was not at all sure that the medical profession was pulling its weight in social economics. The preventive measures, which called for more and more of the doctor's energy, were social economic work of the first order.

On the motion of Dr. Jenner Hoskin, seconded by Professor Lucas Keene, a vote of thanks was accorded to Lord Horder for his address.

MOTOR CARS FOR 1939

THE EARL'S COURT EXHIBITION

[FROM OUR MOTORING CORRESPONDENT]

This year's International Motor Show, the thirty-second organized by the Society of Motor Manufacturers and Traders, which opened on Thursday, October 13, and will continue until Saturday, October 22, is for the second time taking place at Earl's Court, London, S.W. While in the aggregate the number of exhibitors is rather less than last year, it will be found that the international character of the show is well maintained. The productions of fifty-eight different car manufacturers are displayed, of which half are British, the remainder representing the principal automobile productions of Belgium, Canada, France, Germany, Italy, and the United States.

Some Modern Trends

Generally speaking, it may be said that there are no startling departures in the design and construction of cars, manufacturers having been content to continue their 1938 models with minor modifications and improvements in the chassis details, in the bodywork, or in many cases in both. A feature of the new models, however, is the attention which has been paid to the question of securing greater fuel economy—that is, more miles to the gallon of petrol—than hitherto. This is being achieved not only by improvements in engines and carburetors, but also by a reduction in the weight of cars and their chief components. Various recent tests of 10-h.p. cars conducted under official supervision have shown fuel consumption rates of 47½ m.p.g. to be possible, with 40 m.p.g. as quite an easily attainable figure. As a result of the high cost of steel and other raw materials it was expected that manufacturers would have to increase their prices. Some of them have done so, but several of the big concerns, such as Austin, Hillman, Morris, and Standard, have found it possible to offer certain of their productions at slightly lower prices than last year. Whether dearer or cheaper, it cannot be doubted that by reason of the various detail improvements and the very complete range of accessories and conveniences now included in the price 1939 cars are excellent value for money.

Mechanical Modifications and Improvements

All the cars shown, except two makes, have engines with four, six, or eight vertical cylinders, the exceptions being the Jowett, which remains faithful to a two- or four-cylinder horizontal power unit, and the German D.K.W., the only car at the exhibition with an engine working on the two- instead of the more familiar four-stroke principle. So far as cars of from 12 to 14 h.p. are concerned, the "craze" of two or three years ago in favour of six-cylinder engines would appear to have died out, the popularity of four-cylinder power units for this type of vehicle being more noticeable than ever, a notable newcomer to the class being the Vauxhall Twelve-Four, which replaces a six-cylinder car of this

power. This reversion to engines with only four cylinders is due both to improved design of the engine components and to the greater use of rubber in fixing the power unit in the chassis with the object of overcoming vibration.

It is interesting to notice, despite the continued progress of the Diesel or heavy-oil engine in the case of motor omnibuses, coaches, and commercial vehicles, that petrol, benzol, and mixtures of these spirits continue as the fuels for the power units of cars in Great Britain, although in France a few makers are now supplying one or more models with engines using heavy oil instead of petrol.

Synchromesh Change-speed Gears

On British cars gearboxes with four forward speeds are now usual. American cars and a few of English manufacture, on the other hand, have only three speeds, but the gear ratios are so chosen that satisfactory results are given in practical use. During the summer of 1937 there were many references in the motoring press to the probable introduction of "two-pedal" car control, making clutch action automatic and so rendering the familiar clutch pedal unnecessary, and the 1938 meeting of the British Association was notable for the publicity given to a gearless transmission designed to do away altogether with the usual clutch and gearbox. Although one or other of such innovations in car design may in time become general, the present show gives no signs of early departure from current practice. The Daimler and Lanchester concerns still retain the fluid flywheel system of transmission, and the Armstrong-Siddeley the self-changing gearbox, but it would appear to be generally agreed in motor engineering circles that the improvements effected in synchronized change-speed gears have very largely done away with the difficulties formerly experienced with gear-changing.

This year, too, not so much is heard of "over-drives," or something more than the usual direct top gear, for use on level open country roads. These devices, although provided on a number of American cars, are still the exception rather than the rule. The Rover company continues to provide a free-wheel device in conjunction with a four-speed synchromesh gearbox, but there appear to be no new converts among car manufacturers to the free-wheeling idea.

Independent Front-wheel Suspension

Independent front-wheel suspension in place of the usual longitudinal semi-elliptic springs is increasing in popularity, it being found on several more makes of cars than last year, notable additions being the 20-h.p. Armstrong-Siddeley, the 8-h.p., 10-h.p., and 12-h.p. Standards, and the 10-h.p. Sunbeam-Talbot. Improvement in car suspension, giving easier and more comfortable riding, is also said to be secured by what are known as torsion bars in connexion with the chassis springs. The front-wheel drive, while still found on the B.S.A. Scout and Citroën cars, does not appear to have proved popular in this country, a back axle driven by a propeller shaft and spiral bevel or worm gearing continuing the order of the day. This year there is a novelty in a Mercedes-Benz "Colonial" car embodying an all-four road wheel drive and steering.

Attention continues to be devoted to providing cars with powerful, reliable, and easily adjustable mechanical or hydraulic brakes. "Easy-to-clean" steel-spoked road wheels are now generally adopted, and another good point on many of the 1939 cars is the use of larger section tyres. The number of cars fitted with adjustable steering wheels and permanent jacks is increasing, the jacks proving useful not merely for wheel-changing when punctures—now very rare owing to the reliability of modern tyres—are encountered, but also for raising the road wheels clear of the ground during car- and chassis-cleaning operations. It is also satisfactory to find an

extension of the use of grouped chassis lubrication points, which is an advantage to those who still prefer to look after their own cars.

Body Designs

The show is again largely one of covered cars, either saloons or coupés, very few open vehicles being seen, and these mainly for the sporting motorist. For family use the saloon type of body is still the most popular, but for doctors and other professional men, as well as for touring purposes by two people, the drop-head coupé is rapidly growing in favour. The freak designs in streamlined bodywork prevalent a few years ago are now conspicuous by their absence, designers having apparently settled down to a slightly sloped front and rear, with luggage and spare wheel receptacles in the latter. Though "minor modifications and improvements" form the keynote of the show, this is not to say that changes are not slowly but surely taking place. Thus the idea of doing away with the usual chassis frame and securing the engine, gearbox, and transmission directly to the steel frame of the body, as inaugurated by the Citroën company, or the combination of chassis and body frames introduced a year ago in the 10-h.p. car of the Vauxhall company, is slowly progressing, this principle having been applied to the new 12-h.p. and 14-h.p. Vauxhalls and, for the first time, to a Morris car—the newly designed Ten.

In addition to those already mentioned, among the new cars which will be found worthy of inspection are the 16- and 20-h.p. Armstrong-Siddeleys, the 28-h.p. Austin, the B.S.A. Scout 10-h.p. saloon, the Daimler Fifteen, which now has an 18-h.p. engine, the Fiat Twelve, the Humber 27-h.p. Super Snipe, the Jensen eight-cylinder model, the 11.9-h.p. and 12.9-h.p. Lea-Francis cars—these, like the Jensens, being newcomers to the show—the 2.6-litre M.G., the new Morris Ten with integral chassis and body frame, and the new 8-h.p. Morris, the Rover six-cylinder Fourteen, the new 8-h.p., 10-h.p., and 12-h.p. Standards with independent front-wheel suspension, the 10-h.p. Sunbeam-Talbot, the four-cylinder Vauxhall Twelve, and the latest 14/60-, 16/65-, and 18/85-h.p. Wolseleys.

Better Seating and Leg Room

The practice of locating the front and rear seats between the axles to afford more comfortable riding, especially in the larger cars, is increasing, and on some vehicles the front seat is being made wide enough for two passengers in addition to the driver. Minor improvements continue to be introduced in the seats themselves, those at the front now usually having tubular frames which can be adjusted for height and tilt as well as with regard to the amount of leg room available for drivers of different stature. The new tubular seat frames have, too, the advantage of providing space below them for an attaché case or other light articles. Even on what may be termed small cars much greater passenger space is provided than was the case a few years ago, and in a number of such vehicles the rear seat flooring is now quite flat instead of having foot wells. Instrument boards continue to show improvements, the instruments being centrally grouped so as to leave space for large cubby-holes. Indeed, on a few cars a shelf extending over the full width of the instrument board is now being provided.

Some Criticisms

In most covered vehicles attention is still being paid to the problem of preventing fumes from the engine entering the interior and to making better provision for ventilation. The practice of providing for winter use interior heating apparatus of one kind or another is also extending. Notwithstanding all the attention which is being directed to the question of comfort, the designers of motor vehicles would appear to be overlooking the needs of owner-drivers and forcing them to take their cars to service stations for any adjustment, lubrication, or

cleaning that may be necessary from time to time. Motor vehicle components needing regular attention never were as accessible as they might be, but the situation is, if anything, worse to-day than it was a few years ago. Thus, front mudguards now extend so far round the road wheels that it is practically impossible to get at the lubricators of the steering pivots without lying on the floor. Another practice that does not recommend itself to many owner-drivers is unfortunately being continued—that of locating the radiator filler cap below the engine bonnet instead of externally in the top centre of the radiator as in earlier years. Radiators do not often need replenishing with water, but when they do it is a nuisance to have to raise the engine bonnet, and, if one is not careful, there is the added annoyance of spilling water over some of the engine components. Rear number plates are still often so incorporated in the bumper, with tail lamps extending beyond the bumper, that in the case of a "bump" from a following car it is the glass of the number plate or of the tail lamp which suffers the first damage. One writer has lately gone so far as to state that on some cars it is necessary to remove the off-side front road wheel and also a detachable plate on the mudguard valance before the engine valves can be got at! This may not affect those owners who live in towns and cities where service stations are many, but there are still many car users living in remote areas where the nearest service station is several miles away. There appears, too, to be an increasing tendency to locate accumulator batteries under the engine bonnet instead of below the floor boards, a location which certainly provides greater accessibility, although in the opinion of some experienced motorists the under-bonnet position is not without drawbacks to the battery itself.

In view of the many instances reported of bags containing special drugs and instruments being stolen from doctors' cars, a motorist writing to the *Autocar* mentions that no car manufacturer has as yet designed a special "Doctor's Model," and goes on to suggest that a small lock-up cubby-hole capable of taking a medical man's emergency case should be provided on the instrument board, with an accessible compartment in the rear of the car, under lock and key, for more bulky apparatus. On the other hand, another doctor considers that anything which needs locking and unlocking—even the car doors—is not the ideal solution of the problem owing to the time taken up in having to use a lock and key.

Wireless Sets for Motor Cars

Evidence of the increase—although still slow as compared with what obtains in the United States—in the use of wireless receiving sets on motor vehicles is afforded by the fact that for the first time car wireless sets are being exhibited at the show. In accordance with the conditions laid down by the exhibition organizers only sets that have been designed and constructed specifically for motor-car installation, and that are recommended by the particular makers as being suitable for installation on their models, are displayed. There is as yet no car on which a wireless set is included in the list price, but several models are being supplied with one or other form of aerial built into the bodywork in order to facilitate the installation of a set if desired by the car purchaser.

Among the Accessories

The galleries at the Earl's Court exhibition building are again devoted to an array of special fittings and accessories. In view of the latest motor lighting regulations chief interest probably lies in the lamps designed to conform with the legal requirements which now apply to old as well as to new cars. Purchasers of new vehicles will have no difficulty as regards these regulations. In the case of old cars, however, it is for the owners to make themselves acquainted with the most satisfactory and convenient ways of converting their lamps in order that they

may comply with the law. There are also many examples of lamps specially adapted for driving in fog. What are known as "pass lights," with flat-top beams, have been introduced in connexion with the headlight dazzle-preventing problem as a substitute for dipping headlamps, a single control switching off both headlights and simultaneously bringing into operation the "pass light" when passing other cars after dark.

In the tyre section there are one or two new exhibits worthy of special mention. The Goodyear company has introduced a new inner tube known as the "lifeguard," the feature of which is that the tube has formed within it a supplementary two-ply fabric tyre, the two being so connected as to be inflated through the one valve. The object of the new tube is to avoid accident, and serious damage to the main outer cover, in case of tube burst or puncture, the resulting loss of air from the ordinary tube being slowly replaced from the reserve supply in the extra tube through a vent. It is claimed that should a burst or puncture be experienced, even when travelling at high speed, cars having tyres fitted with the new "lifeguard" can be relied upon to run under perfect control from one-half to three-quarters of a mile, allowing the driver ample time to bring the vehicle safely to a stop.

Finally, it may be mentioned that the exhibition is open daily, except Sunday, from 10 a.m. until 10 p.m., and that the price of admission is 2s. 6d., except on Tuesday, October 18, and Thursday, October 20, when it is 5s. up to 5 p.m. and 2s. 6d. afterwards. The Ford company is not this year holding its usual exhibition at the Albert Hall, Kensington. It is proposed, in next week's issue, to follow the customary plan of referring to some of the new cars in more detail, especially those likely to appeal to medical men from the point of view of suitability, reliability, and both purchase and subsequent maintenance costs.

C. J. W.

RESISTANCE TO EXPERIMENTAL CANCER

SIR FREDERICK BANTING'S LECTURE

The Barnes Hall of the Royal Society of Medicine was filled on October 11 when Sir Frederick G. Banting, F.R.S., of the University of Toronto, delivered the second W. E. Dixon Memorial Lecture. His subject had been announced as "The Immunity Aspect of the Tumour Problem," but he altered this on delivery to "Resistance to Experimental Cancer."

Sir Frederick Banting began by remarking that in 1925 he visited the laboratory of Dr. Gye, and since that time his main interest in medical research had centred around the cancer problem. Many experiments had been performed in his own laboratory, and although he realized that to report experiments on cancer in London was carrying coals to Newcastle, he desired to present to his audience some of this work. The original title of his lecture mentioned "immunity," but until it was finally proved that cancer in general was due to a virus or living agent it was better to use the term "resistance," although the other term was permissible in the case of filterable fowl tumours which had been shown to be due to a virus.

It was impossible to give even a brief review of the immense literature on this subject. Before 1903 workers in isolated laboratories had made observations on tumours in animals, especially mice, and had transplanted fragments of tumour into other mice, thus carrying the tumour strain; but it was not generally accepted that these scientific curiosities had a very close relationship to the tumour problem in man. With the establishment of the Imperial Cancer Research Fund co-ordinated research on cancer was started, and to the original group of workers under those auspices and to their successors the world would always owe a deep debt of gratitude. It was they who first

established the fact that cancer was fundamentally the same in all animals and in man. They studied many strains of transplantable tumours in many different species of animals, and their observations formed the basis for much of the subsequent research.

Earlier Work

The early experimental work on mammalian tumours demonstrated clearly that tumours in animals were identical with tumours in man in respect of mode of origin, age incidence, clinical course, mode of growth, and infiltration of surrounding tissue. Transplantation could only be carried out within the species; there was a strict specificity. Tumours could only be propagated by the transplantation of living cells. Until 1909 these constituted the most important of the facts known. During the next decade, however, the work of Rous and his associates and that of Japanese investigators changed the course of the inquiry. An outstanding point was that a variety of chemical agents would induce tumour, and once the tumour was induced the chemical no longer operated in the perpetuation of the growth. From the aspect of resistance, therefore, chemically induced tumours did not differ from mammalian tumours.

In 1910 Rous and others found a number of sarcomas which could be propagated in fowls by means of a cell-free filtrate. At first most pathologists considered these tumours to be due to inflammation, and not to be true sarcomas, but on further investigation they had become accepted as genuine cancer. Rous sarcoma No. 1 was one of the most universally used laboratory tumours. With this tumour Gye had done most of the work on his specific factor theory. In every way the Rous sarcoma was identifiable with mammalian tumours.

Since 1926 a study of the Rous sarcoma had been undertaken in the lecturer's laboratories at Toronto. The birds used were fully grown chickens from 6 to 12 months old. The age of the bird was an important factor, because in young birds Rous sarcoma developed more rapidly and killed more readily than in older ones. Gye used young chicks and found, out of 6,000, only one in which the tumour regressed. In the work in the lecturer's own laboratories transplants were made into the muscle of both breasts with a trocar 2 mm. in diameter. When tissues were required for transplantation the chicken with the most rapidly growing tumour was killed; the bird with the more slow-growing was allowed to live. During the six years from 1928 to 1934, 1,768 chickens were transplanted. Of these, 621 were killed to obtain tumour tissue, and of the remaining 1,147 birds, 1,140 died of tumour. Seven birds—1 in 164—became resistant to Rous sarcoma. The resistant bird by his definition was one in which a well-established tumour regressed; on additional transplantation a second small tumour might develop, but this also regressed; tumour did not develop on subsequent transplantation, and the bird did not die of tumour.

Experiments on the Rous Strain

During the past ten years in his laboratories 6,000 fowls had been used for experimental work on the Rous sarcoma; 118 birds, or 1 in 50, had shown some degree of resistance. Of the 118 birds, forty-four had received more than five direct transplants and remained negative, some of them being kept in the laboratory for as long as five years, during which as many as forty transplants were made. The thirty-eight which had died showed no sign of tumour on necropsy, and the other six were still alive and well. In twenty birds a tumour of large size regressed, but on subsequent transplantation the birds again developed tumour and died. One bird, which had developed five large tumours, died as a result of the fifth, the first four having regressed. Instances had been observed in which a large tumour in one breast had almost disappeared, but direct transplant or injection of

tumour extract into the opposite breast caused a rapid growth of the original tumour.

From the earliest work on transplantation it had been observed that the size of the transplant had an important bearing on the result, and it was thought that probably a tumour could be produced in a resistant bird by administration of a large dose of active tumour cell. A bird was given 6 c.cm. of finely divided tumour cell—a dose estimated to produce sufficient tumour-containing substance to kill 6,000 birds—and did develop a tumour, but two weeks later the tumour was absorbed, and the breast into which the injection had been made was quite normal. One of the first signs of regression was often the appearance of the bird. The comb became red and there was an increase in weight even while the tumour remained large.

Very early in the investigation it was found that the plasma of Rous-resistant birds neutralized the cell-free active filtrates of a Rous tumour. More than forty experiments on these lines had been carried out. In the earlier ones 2 c.cm. of resistant plasma was used to neutralize 1 c.cm. of potent extract; in later work only a fraction of 1 c.cm. of plasma was necessary, probably owing to the hyperimmunity developed by resistant birds as a result of repeated tumour-cell inoculation. From the fact that large amounts of highly immune plasma had no effect on the growth of the tumour it would appear that the virus, being within the cancer cell, was not affected by the antibodies in the blood. When Rous cells were injected into the resistant bird the cells died and were absorbed. Did they die from lack of blood supply, or were they killed by the antibodies of the blood? The point whether or not the tumour cell membrane could afford an absolute protection to the virus against the immune serum was an important one and required further investigation. Experiments were also made in which the tumour extracts were mixed with an immune bird plasma and injected at the same time. It was found that one or two out of three birds so injected always developed the tumour, suggesting that the immune plasma required time for the neutralization of a virus. Further experiments showed that it was necessary to give approximately 30 c.cm. of resistant plasma in order to protect a bird against the injection of 1 c.cm. of a potent tumour extract. The plasma when injected into the body was diluted by the blood and other body fluids, and unless large quantities of the serum were given there was not enough concentration at the site of inoculation to bring about protection of the local cells. All tissues of a resistant bird appeared to be resistant both to cell-free filtrates and to Rous tumour cells.

Cross-immunological Reactions

Since 1933 there had also been available for study Fuginami strains of filterable fowl tumours. These tumours could be propagated in both chickens and ducks. They showed a much greater tendency to regression than the Rous. For these experiments 180 birds had been used. Of this number 158 died of tumour or were killed for transplants, while 22 showed some degree of resistance. This was 1 in 8, as compared with 1 in 51 in the case of Rous sarcoma. Twelve birds which were resistant to Fuginami were inoculated with Rous extract or cells, and ten of them developed Rous tumours and died, while the other two became resistant to Rous as well as to Fuginami.

Although the Fuginami tumour had not been studied as extensively as the Rous it would appear that there was a similar variation in the degree of immunity in the two tumour strains. The regression of one tumour did not always mean that there would not be the development of another tumour on subsequent transplantation. Two of the Rous-resistant birds were given an extract of dried Fuginami tumour. One of them had been under observation for three years previously and had remained negative

to many Rous transplantations. Both these birds developed large tumours following the Fuginami inoculation and died from secondaries in the lung. Blood was obtained from the heart of one of these birds at necropsy and the plasma was found completely to neutralize Rous sarcoma extract. This indicated that these birds remained resistant to Rous tumour although dying of Fuginami. It was also found that the plasma of a Fuginami-resistant bird could neutralize Fuginami cell-free extract, but did not resist Rous extract.

Production of Dibenzanthracene Tumours

Sir Frederick Banting proceeded to describe a further experiment in which twelve Rous-resistant birds and twelve normal birds were each given three injections of 5 mg. of dibenzanthracene. Four of the twelve resistant birds were given Rous transplants at intervals throughout the experiment and they remained negative to Rous. Six of these resistant birds developed dibenzanthracene tumours and six remained negative. Of the normal birds eight developed the tumours, three remained negative, and one died of other causes. Evidently a high degree of resistance to Rous did not protect the bird against the development of dibenzanthracene tumour.

In the periodic examination of birds with growing tumours there was sometimes encountered an exudation of fluid in the skin overlying the tumour. This fluid on being drawn off did not give rise to tumour when injected into other birds, but had a neutralizing effect equivalent to that of resistant serum when added to tumour extract.

Many attempts had been made to immunize a fowl to Rous sarcoma. The birds had been given repeated injections of neutralized or partially neutralized serum of the tumour extract mixtures. Owing to the many failures to produce with constancy even minor degrees of resistance to Rous sarcoma, it was thought that the production of resistance or immunity might be connected with the tumour cell itself. Experiments were therefore prepared with the object of killing the tumour cell by physiological means so that the hypothetical antigenic properties might remain. It was decided to use ammonia for this purpose as it was a by-product of cell metabolism. But the cells thus treated, even when 20 per cent. ammonia was used, gave rise to tumours when injected into normal birds.

Various efforts to produce resistance to Rous tumour were described, including the repeated administration of neutralized mixtures of virus and serum, and immunization by the injection of tumour cells killed with glyceric aldehyde. In this last procedure the cells were suspended in a 4 per cent. solution of glyceric aldehyde and shaken at intervals of three hours. Of the birds injected, three developed tumours and died in the usual time; two others developed tumours which regressed, but on re-transplantation the tumours developed again and the birds died; the remaining bird did not develop a tumour until it received a transplant, when a tumour developed, and the bird died in twenty-five days. The finding was that the injection of cells treated with glyceric aldehyde did not promote the formation of antibodies against tumour, though when the cells had been exposed to dilute solutions of glyceric aldehyde in some cases the tumours were more slow-growing and the bird recovered.

Concurrently with the work on the chicken filterable tumours, certain experiments and observations had been made on three strains of mouse tumour, but with no very satisfactory results.

General Conclusions

Sir Frederick Banting said in conclusion that all this experimental work required a large number of animals, including controls, and a great deal of time, and there was such great variation in the individual animal or bird that the results were often difficult to interpret. The outstanding feature of the cancer problem was the specificity

of the disease. Cancer was identical in the fowl, the mouse, and man, yet the disease could not, with few exceptions, be transmitted outside the species. Resistance to cancer was even more specific. The work to date did not appear to contribute much towards specific treatment. The terms "immunity" and "resistance" were used in association, although, as he had pointed out at the beginning, they referred to different conditions. "Resistance" indicated refractiveness to grafted cells; "immunity," the condition under which the animal was able to combat, perhaps destroy, the intracellular growth.

The balance of evidence suggested that what he had called resistance was a laboratory phenomenon unrelated to cancer of spontaneous nature. It might be simply an indication of reaction between host and tumour cells. If this were the complete explanation of the phenomenon of resistance it could scarcely be imagined that the forces which destroyed a transplanted tumour could ever operate in natural cancer, in which the malignant cells had necessarily the same genetic constitution as the host. But after some of these experiments there lurked in his mind the notion that the forces which effectively rid an animal of a spontaneous tumour might be a combination of intracellular and anti-viral immune bodies. The spontaneous cure of natural cancer was very rare, but there had been experimental tumours which could be propagated with cell-free filtrates and were therefore the equivalent of spontaneous tumours, and these under certain circumstances regressed. The question was whether the regression was brought about by the development of immune bodies which destroyed the virus, or whether it was a more complex process, an interplay of various factors determining either an unlimited growth of the tumour or regression.

The opinion derived from this work was that antigenic differences between host and malignant tissues might be sufficiently great to stimulate antibodies adequate to ensure the disappearance of even spontaneous cancers. It was along these lines that the greatest hope of cancer therapy lay.

Medical Notes in Parliament

Tuberculosis in Newfoundland.—MR. MALCOLM MACDONALD, answering Mr. W. Gallacher on October 5, said a survey recently carried out suggested that the incidence of tuberculosis in Newfoundland was about 6,600 cases per 100,000 of the population. Steps had been taken recently to enlarge the tuberculosis sanatorium and to inaugurate special measures to control and prevent the spread of this disease.

Staffordshire County Hospitals.—MR. MANOER asked on October 6 what the arrangements were for hospital treatment for persons resident in Wednesfield and Willenhall organized by the Staffordshire County Council. MR. BERNAYS replied that the county council was proceeding with the reorganization of its hospital arrangements, and the present situation did not, to its knowledge, give rise to any difficulties. An assistant medical officer resided at Wordsley Hospital, the medical officer lived in the immediate vicinity, and the services of specialists were available if necessary.

Those medical practitioners whose approval for the purpose of signing recommendations under Sections 1 (3) and 5 (3) of the Mental Treatment Act, 1930, expires on December 31 next are being invited by the Board of Control to make application for the renewal of the approval and are being furnished with forms of application for this purpose. Any other practitioner who may desire to seek approval under the Mental Treatment Act can obtain a form of application on writing to the Board of Control, Hobart House, Grosvenor Place, London, S.W.1.

Local News

SCOTLAND

New Edinburgh Professor

The chair of chemistry in relation to medicine in the University of Edinburgh, rendered vacant by the transfer of Professor Barger to Glasgow, has been filled by the appointment of Professor G. F. Marrian, D.Sc. Professor Marrian is at present associate professor of biochemistry in the University of Toronto. After studying at University College, London, and at the Medical Research Laboratories, Hampstead, he received his present appointment in 1931. He is well known for his research on the isolation of oestrin, and he is one of the leading authorities on the investigation of sex hormones, which he has carried out at Toronto.

Honyman-Gillespie Lectures

A series of eight lectures in medicine will be delivered during the autumn term in the Royal Infirmary of Edinburgh on subjects selected in relation to the weekly teaching in an intensive course on internal medicine to be held during the same period. The lectures will be given in the West Medical Theatre at 5 o'clock, and all medical practitioners are invited to attend. The lectures are as follows: "The Rational Use of Digitalis," by Dr. A. Rae Gilchrist; "Neurology—Some Modern Problems," by Dr. W. Ritchie Russell; "Psychotherapy," by Dr. T. A. Ross; "Emphysema," by Professor R. V. Christie; "Hepatitis," by Professor J. W. McNeer; "Protein in the Treatment of Nephritis," by Dr. J. D. S. Cameron; "The Significance of Glycosuria," by Professor D. M. Dunlop; and "The Mechanism of Megaloblastic Blood Formation," by Professor L. S. P. Davidson.

Memorial to Dunbar Doctor

A bronze plaque with portrait medallion to the memory of the late Dr. Duncan R. Macdonald was unveiled on October 2 in the Dunbar and District Cottage Hospital. Professor P. O. Turnbull presided at the ceremony, and paid a tribute to Dr. Macdonald's services to the community of Dunbar and especially his work in the service of this hospital. Several hundred pounds had been collected for the memorial from Dr. Macdonald's friends and patients, and the sum collected sufficed to endow a bed in the hospital as well as to furnish the memorial plaque.

ENGLAND AND WALES

A.R.P. in London: Hospital and Ambulance Services

A special meeting of the London County Council was summoned on October 7 to discuss a report presented by the Air Raid Precautions Subcommittee, the chairman of which is Mr. Herbert Morrison, M.P., the leader of the Council. The report which Mr. Morrison submitted dealt mainly with three subjects: emergency fire brigade organization, the evacuation of school children, and the casualty service. With regard to the last of these, the new arrangement whereby the Ministry of Health assumes responsibility for the organization of all hospitals (clearing stations or base hospitals) for the reception of air raid casualties, although not yet embodied in formal regulations, was during the recent emergency put into operation. Two of the Council's medical staff were seconded to the Ministry in connexion with the organization of the casualty scheme, which embraces London and the home counties. Among

the measures taken were the purchase of 10,000 supplementary beds and 20,000 blankets, and the upgrading of nearly all the L.C.C. fever hospitals to the status of full surgical hospitals on an emergency basis by the purchase of additional equipment. Provision was made for emergency stocks of drugs, dressings, and serums to be maintained at all hospitals which would be used under the casualty scheme. Material was also obtained for the darkening of all hospital windows, which are normally entirely without blinds. Sufficient respirators were issued for both patients and staff. The Ministry of Health having assumed responsibility for the organization of ambulance transport in connexion with the London casualty scheme, the officer in charge of the London ambulance service was, at the Ministry's request, seconded to the Ministry. For the augmentation of the service some 2,000 vehicles were required to be adapted as emergency ambulances, and 5,000 women drivers were needed. To augment the number of vehicles available in time of war, equipment has been urgently manufactured to enable the fleet of sixty-nine vehicles used for the conveyance of children to and from special schools to be adapted within a few hours as ambulances. Arrangements were made with the London Passenger Transport Board for a large number of motor coaches to be similarly adapted. A supply of respirators for ambulance drivers and attendants was obtained from the Home Office. An organization was set up for the decontamination and repair of any damage which might be occasioned to the main drainage system in the event of war. For this purpose trained squads of men were formed from the L.C.C. main drainage staff.

In our *Supplement* this week will be found at p. 248 an account of the preparations made by the L.C.C. Hospital Service to meet the emergency had it actually occurred.

Correspondence

Civil Medical Organization in War

SIR,—Last week you published a leader on the medical arrangements needed for dealing with intensive air raids upon London. In that article it was stated that a medical committee had been appointed by the Home Office immediately after the earlier crisis of May 21, that it had worked strenuously under the chairmanship of Sir Charles Wilson, and had completed before the end of July an interim report on the methods that could be adopted for dealing with air raid casualties throughout London. Comment was then made on the fact that when September brought its graver crisis, civilian hospitals were still without Government instructions as to their precise place in the scheme of medical work.

The authorities at University College Hospital received on September 14 the information that the hospital would be expected to act as a casualty clearing station. No other instructions had been given, and the only official information to guide action was that of the A.R.P. handbooks. Thanks to the Army experience of some members of the staff who had served in France during the last war, and still more to the keenness of everyone else, the hospital stood ready for its new work by midday on Thursday, September 29. Half the in-patients had been evacuated. A complete schedule of new duties had been worked out for students, nurses, and staff with lists by name of the various teams on duty or for relief, and with precise instructions as to the place where each team would work. The operating theatres in the unprotected top floor of the hospital were replaced by extemporized provisions at a lower and safer level. A blood transfusion service was

completely organized with new apparatus all assembled, the material having for the most part been given by the science laboratories of University College, and it could have provided for a hundred transfusions a day; 250 volunteers from students were typed to act as donors, and the names of nearly 500 other volunteers in the neighbourhood were registered. The hospital was ready to work as a casualty station, but no central authority had asked for any report on the progress or completion of arrangements.

One general defect is now evident as the preparations made locally at one hospital in that busy week are being reviewed. The method of recording clinical notes at length in case sheets, as used in most of the voluntary hospitals, would have broken down completely under the strain of admitting 500 or more casualties a day; nor would it have provided the clinical records that must accompany each casualty when he is moved rapidly from one post to another in a hospital, and later moved to a base hospital elsewhere. As a temporary device, quantities of luggage labels were bought, and they were to be stamped for such entries as name and diagnosis, dose of A.T. serum or morphine, etc.

If payment is to be made to voluntary hospitals for the number of civilian air raid casualties admitted, and particularly if compensation is to be given later to the individual victims of air raids, it will be essential to have all the main data about each casualty noted down in a uniform style on some cards issued by Government and belonging to Government.

During the war it was soon found that the old system of case sheets retained in each military hospital was inadequate to give the clinical information needed during the rapid transport of casualties, especially from France to the United Kingdom; but two years were allowed to pass before a satisfactory system based on small transport and index cards was evolved. Perhaps the method now intended for use by the R.A.M.C. in time of war could readily be adapted for civilian war casualties, and the Home Office Committee may have advised on this point. If so, it would be a small expense for the necessary cards to be printed at once and issued to the various hospitals. They would have an important effect as a token of the co-ordinated work that the hospitals must now definitely prepare themselves to undertake. All that University College Hospital received from the Ministry of Health was a stencilled example, copies to be made somehow and completed in triplicate, of a discharge certificate used for the Ministry of Pensions, beginning, so to speak, with the end of the story.—I am, etc.,

T. R. ELLIOTT.

University College Hospital,
W.C.1, Oct. 10.

SIR,—Your leading article on air raid casualties (October 8, p. 749) reflects the anxieties which many of us have felt in regard to the care of the sick and injured of London in the event of war. This anxiety particularly applies to the teaching hospitals, which, being independent bodies with large staffs of differing categories and numbers of medical students, must have felt the need for a more comprehensive plan for the utilization of their services than that of evacuation and conversion to so-called casualty clearing stations. A war could hardly lessen the call on their services by the sick, to whom must be added air raid casualties, and mere evacuation does nothing to provide for continued treatment. Further, the training of future doctors would be even more necessary in war than in peace, and could not be provided by casualty clearing stations.

What would seem to be needed is the establishment of large base hospitals, out of the immediate danger zone, either in existing buildings or in huts associated with each teaching hospital. To these could be evacuated existing patients if war became imminent; to them could go patients, either sick or wounded, who presented themselves to the London parent hospital and were found in need of other than immediate treatment. If their sites were correlated with the plans for the evacuation of the non-essential civil population the problems of the medical care of such refugees would be partly solved. The staff of the teaching hospital could serve both institutions, since the personnel needed for a casualty clearing station, even including the provision of mobile surgical teams for use elsewhere in London, would be well within their capacity to provide. The medical students in their clinical period could be divided between the two institutions, and would be of service at the same time as they were continuing their studies.

Such a scheme would entail the employment of the staffs on a whole-time, or almost whole-time, basis, and would necessitate their taking-over and payment directly or indirectly by the State, and the provision of safeguards such as apply to Service officers. Many other allied problems, such as the provision of accommodation for private patients in the presumed event of London nursing homes being untenable, require separate consideration. War has been happily averted for the present, but the provision now of adequate plans for dealing with its many-sided problems, should it occur, is no less necessary however sincerely we may hope it can be avoided in the future.—I am, etc.,

London, W.1, Oct. 8. E. G. SLESINGER, M.S., F.R.C.S.

SIR,—Perhaps we shall never know the magnitude of the widespread failures of the present A.R.P. scheme during the recent period of emergency. It would appear that the policy of the past two years has been mainly to reassure the population that there is no real danger to be feared from the air, if . . . This feeling has been so thoroughly disseminated during a comfortable peace that the man in the street has responded, "Then why worry?" I cannot avoid the feeling that the shortage of volunteers has been due, to some extent, to this cause.

In the *Supplement* of December 26, 1936 (p. 339), you published an article of mine on air raid precautions in which I outlined a scheme of organization, many of the features of which have since been adopted—and many have not. We are only concerned with the medical aspect, however, and before any efficient scheme can be organized there are certain fundamental principles which must be recognized, but seem to play very little part in the existing arrangements.

First, there must be a definitely attested medical personnel of known strength. Secondly, there can be no efficient organization without disciplinary control, trained direction, uniform training, and adequate medical equipment. Thirdly, the A.R.P. medical organization should take the form of a corporate body on national and not municipal lines, directed by senior administrative medical officers practised in the tactical employment of medical personnel during raids; in other words, some form of A.R.P. Medical Corps. The experience of the past few weeks suggests that the whole A.R.P. arrangements also would be better on a national basis.

In my paper quoted above I mentioned the probability of a shortage of doctors and pointed out the need for training the first-aid personnel to a degree of efficiency that would qualify them to render first aid and collect

casualties without medical supervision, so that doctors might be employed in posts where their skilled assistance may be used to the fullest advantage—for example, casualty clearing stations. This would clearly entail a training programme much wider and more thorough than that of the ordinary ambulance class, and it would have to be undertaken by the doctor.

Personnel should be attested under suitably modified conditions of service on the lines of a part-time Territorial Army, a minimum standard of efficiency would be required, with a compulsory annual efficiency test. Although in my paper I did not consider a uniform necessary, if it would encourage recruits by all means let them have one. It would serve to distinguish them, by night as well as by day, as trained men.

If the full story of A.R.P. could be told there would be some amazing revelations of inefficiency. There are still communities without gas-masks. In some cases *laissez faire* and crass stupidity have been incredible. Imagine, for instance, local councils, for reasons best known to themselves, appointing existing officials to the additional duties of A.R.P. officer. In some cases he has been the chief of the fire brigade. It would be difficult to imagine two more incompatible duties than these. In a raid the fire brigade would be so fully occupied with widespread simultaneous outbreaks from incendiary bombs that, being primarily a fireman, his hands would be too full to worry about A.R.P.

It will be interesting to watch developments.—I am, etc.,

H. M. STANLEY TURNER,
Wing Commander, R.A.F.

Brookwood, Oct. 8.

SIR,—The scheme prepared by the Ministry of Health for converting, on the outbreak of war, special hospitals in the Central London area into general hospitals omits any recognition of the fact that nearly every member of the visiting medical staff of a hospital is attached to more than one hospital. Is it left to the surgeon's own conscience to decide which of his hospitals he shall stand by?

The question may become an acute one in a crisis. If war were declared and a Military Service Act passed, the younger men would be called up and, for one reason or another, not excluding possible casualties, many hospitals might find themselves almost denuded of their usual staff. Doubtless in time additional surgeons would be allocated by the Central Emergency Committee of the B.M.A., but such an arrangement would necessarily be less satisfactory than the retention as far as possible of the usual staff.

The problem is a difficult one, but it does seem to call for a clear-cut ruling. Perhaps the best solution would be a general recommendation to the effect that in each hospital a small committee, consisting, perhaps, of the chairman of the hospital, the secretary, and the senior surgeon, be empowered to decide the dispositions of the staff. If this were done now the hospitals concerned could settle by mutual agreement a panel of surgeons on whose services they could rely in case of emergency.—I am, etc.,

London, W.1, Oct. 10.

A. RUGG-GUNN.

SIR,—I agree with every word of your leading article on this subject (*Journal*, October 8, p. 749). I have heard tales of lack of organization from others, but let me state my own experience. Some months ago I offered my services in my home district for casualty work. On Thursday during the week of crisis I found on getting

home, a notice directing me to attend a certain school during an air raid. I went at once to this school: there were no preparations except rubbish bins and a couple of buckets. If war had occurred we might well have had a raid on Saturday or Sunday. Possibly dressings, splints, etc., might have arrived later, but it is obvious that it is no use collecting a certain number of doctors unless they have apparatus to use and unless a team is planned and responsible officers appointed to organize the work. I hope that the British Medical Association will use its influence with the authorities to secure that supplies and organization are ready before the next crisis arises. If the Ministry of Health delegates work to local authorities some medical man should be made responsible for each district and each unit.—I am, etc.,

Late Major, I.M.S.

London, W.1, Oct. 7.

Decline of Breast-feeding

SIR.—Dr. J. C. Spence's paper on the decline of breast-feeding (*Journal*, October 8, p. 729) is so convincing that I entertain the hope that it will do something to "stop the rot." He has set forth the psychological factors involved, but I think there is more to be said on this aspect of the question.

In the more educated sections of the community we are reaching the second generation of bottle babies; in other words, many of the mothers who renounce serious breast-feeding know that they were not themselves breast-fed. Consequently there is liable to be a latent protest: "Why should I take the trouble that mother didn't take for me?" Then there is the relatively new factor of the cigarette habit, and, whether admitted or not, it certainly influences some young mothers in favour of the bottle.

The psychology of the nurse is even more important than Dr. Spence indicates. Most maternity nurses are childless. Most of them have a strong maternal urge. (If they have not this urge they are liable to be second-rate at their work.) The resultant of these two components is an inevitable envy of the mother. In many cases, perhaps in most, it is completely repressed, but that does not prevent it from being operative. The expression of this unconscious envy is, first, to abrogate maternal functions, of which the most important is nutrition; and, secondly, to disparage the mother's capacity. Bad maternity nurses give the mother a sense of inferiority, not merely about lactation, but about every aspect of child management. "Heaven help baby when I have gone!" is a cheery jest which cuts deep. Consciously it may be only a jest; unconsciously it is meant to hurt. Thus the maternity nurse (whether she knows it or not) is prejudiced in favour of bottle-feeding in spite of the fact that it generally involves more trouble for her.

It is largely on the nurse's evidence that the doctor makes his decision. But what of his unconscious motive? Unfortunately most of us are sufficiently like other members of our race as to suffer from self-importance. Of course this regrettable item in our make-up is generally, if not always, hidden from our own eyes. This latent self-importance is the source of much obscurantism, fussiness, and solemnity throughout our profession. It makes us very averse to a policy of non-intervention. The most mischievous form it takes is the solemn warning to the husband of the primipara that a second child must not be risked. A lesser form of interference with Nature is the advice to "put baby on the bottle."

But these unconscious motives which influence the adult culminate in results for the child that are even more

serious than Dr. Spence indicates. Medical psychologists are discovering daily the permanent damage that can be inflicted in connexion with infant feeding. No doubt ill-conducted breast-feeding can cause psychic traumata of great severity. So also can bottle-feeding. It, however, lacks in addition the great opportunity which breast-feeding affords. That opportunity is no less than the conditioning of the nascent social sense. Thereby the infant begins to differentiate the non-ego from the ego under conditions of instinctual satisfaction, physical well-being, and, above all, perfect security. This is the beginning of all sound social adjustment. Though these conditions can to a certain extent be imitated by bottle-feeding they can never be fully reproduced.

I hope that these considerations, in addition to Dr. Spence's cogent arguments, may influence some of our colleagues to refrain from hasty decisions in favour of "Ersatz" feeding of infants, however fashionable it may be.—I am, etc.,

London, W., Oct. 10.

H. CRICHTON MILLER.

SIR,—I was greatly pleased to read the excellent article by Dr. J. C. Spence, and I fully agree with his wish to encourage the natural method of feeding. As a matter of fact it is one of the most important contributions to infant welfare. I would, however, like to draw attention to the question as to how many women are anatomically capable of breast-feeding. Certainly the incidence varies.

At the beginning of my pediatric career the question was much discussed. I tried to find a basis by anatomical investigations, and these were carried out in Dresden and Düsseldorf. Sections were made through the whole breast of women who had died shortly after childbirth. This was done by means of a special large microtome which enabled one to obtain a survey of the distribution of the secretory tissue. Results were uniform in both cities. The amount of glandular tissue varies within wide limits from practically nil (only fibrous tissue being present) to a condition of practically 100 per cent. secretory tissue. On the other hand, in the animals investigated for comparison this variation was not met with.

I mention these findings in order to demonstrate that there are anatomical difficulties in the way of many women feeding their children. Yet I do not quote these results in order to discourage doctors from insisting on breast-feeding. On the contrary, I would urge that it is necessary to encourage the young mother and to give her every help possible in view of the difficulties which arise in many cases.—I am, etc.,

London, N.W.7, Oct. 8.

STEFAN ENGEL.

Prognosis of Anxiety States

SIR,—The article by Dr. Arthur Harris on the prognosis of anxiety states in the *Journal* of September 24 (p. 649) has one curious omission—the absence of any consideration of the treatment employed in the cases he describes. The results obtained by a follow-up of 123 cases, selected from the records of the Maudsley Hospital, are analysed. Thirty-eight are found to have recovered and sixty to be still suffering from anxiety states. His only reference to treatment, however, is a remark that more "energy" was expended before a case progressed from the worst grade of severity to the lightest grade than from the lightest grade to complete health, and that cases which responded rapidly gave the best results, those requiring prolonged treatment being disappointing.

Should we not expect the question of treatment to be a factor vitally influencing the results? If so, is it not necessary to know whether psychotherapy or some other form of treatment was employed, or whether some of the cases had one kind of treatment and some another? If they were treated by psychotherapy, was it merely reassurance and medicine that were given or was a form of analysis and interpretation carried out?

Unless information on these points is forthcoming can we look upon the results described by Dr. Harris as of value in enabling an opinion on the subject of prognosis to be formed? Is it possible, however, that he means to imply that treatment is not significant in estimating the prognosis in anxiety states?—I am, etc.,

London, W.I, Oct. 8.

FREDERICK DILLON.

Vasomotor Rhinorrhoea

SIR,—In your issue of October 1 (p. 703) Dr. A. S. Heseason makes a valuable contribution to the study of the fascinating problem of vasomotor rhinorrhoea and conditions secondary to the allergic nasal mucosa. The importance of his paper, in my opinion, lies in the fact that he has linked up recent advances in endocrinology with the experimental work of Myers on the nerve paths involved in the "naso-pulmonary reflex." I have myself encountered only four cases in which rhinorrhoea, asthma, and menstruation were definitely associated, so that I am unable at present to estimate the incidence of this condition; it would be interesting to hear of the experience of other workers in this field.

With regard to food sensitivity, my experience is that skin testing for this is of little value, since so many subjects are allergic to breakdown products of digestion, which skin-testing may not show; skin or mucosal tests for other allergens can be relied upon if properly carried out. For the investigation of food sensitivity the climatic diets given by A. H. Rowe in his book *Clinical Allergy* are to be preferred.

The diagnosis of nasogenic asthma is generally easy if the cocaine spray can be employed during an attack, but, as always, an accurate "history" with particular regard to the duration of symptoms and age of onset is essential. Dr. Heseason rightly sounds a note of warning lest in cases of asthma and bronchitis the allergic condition be overlooked and treatment directed solely to the secondary bacterial infection. The same applies to cases of so-called "nasal catarrh."—I am, etc.,

London, W.I, Oct. 4.

CLIVE SHIELDS.

Function of Epithelial Cells

SIR,—The epithelial cells in the body have two well-known functions: (1) to cover and protect surfaces exposed to injury; (2) to secrete substances necessary for normal growth and metabolism. They have in addition other activities, which I think require more consideration and investigation—namely, the reactions which they cause on contact with other tissues, and also their reactions to abnormal contact with body fluids.

The syncytial epithelium of the ovum where it comes in contact with the uterine mucosa causes destruction of the epithelial and proliferation of the connective tissue elements, and when it comes into contact with the capillary endothelial lining fuses and comes into direct continuity with it.

In the process of healing, the epithelial cells, as they flow over a granulating surface, graft themselves to it by formation of a basement membrane. I hold that the

formation of a basement membrane is caused by the action of a secretion of the epithelial cells on the cells of the granulation tissue. My reasons for this view are that in different places the basement membrane is modified to suit the particular requirements of the situation, and in healing after injury—if the injury is not too extensive—there is an effort to re-form the same type by resolution of the scar tissue. For instance, an extensive corneal opacity can clear up in a healthy child.

The basement membrane is also in my opinion a very important factor in the normal nutrition, health, and growth of epithelial cells. Its rupture by injury and consequent escape of circulatory fluid allow direct contact of that fluid with the epithelium, and this abnormal contact causes active proliferation of its cells necessary for repair. The abnormal proliferation ceases when continuity of the basement membrane is again established.

I think from this that there is reason to believe that substances in the body fluids which tend to cause abnormal generative activity in the epithelial cells are kept apart from them or altered by the basement membrane.—I am, etc.,

Magherafelt, Co. Derry, Sept. 26.

P. HEGARTY.

Traumatic Amputation of Finger

SIR,—In regard to Dr. W. D. Park's letter in the *Journal* of September 24 (p. 680), discussing treatment of the guillotine type of traumatic amputation of the fingers, I agree that re-amputation at a higher level to obtain skin flaps is usually contraindicated. Of late I have treated cases by the immediate application of a thick Thiersch graft with pressure dressing. This has given satisfactory results. The return to work is quicker than with any dressings (usually flavine cream dressing) I have seen used, although I have not had any experience with tannic acid as described. The resultant scar contains less fibrous tissue and the graft usually takes well, in spite of the bare bone.—I am, etc.,

London, E., Oct. 8.

C. LAURENCE HEANLEY,
Surgical First Assistant, London
Hospital.

A Dressing for Wounds

SIR,—Regarding the sterilizing (approximately) of accidental wounds I should like to recommend a solution of iodine in glycerin or in glycerin and boric acid. (The latter is considerably denser.)

Used at a strength of $1\frac{1}{2}$ drachms of the strong tincture in a pint, it is applied on a gauze packing that can be left in the wound for anything from twelve to twenty-four hours. This follows the preliminary treating of the wound with a more diffusible antiseptic, and the glycerin, whatever antiseptic it carries, provokes a very useful exudation, and secondary suturing or strapping may often be carried out. It is not, however, a good dressing to go on with, as glycerin, unless quite dilute, tends to retard healing, causing, for example, haemolysis, as has been observed experimentally (by Dr. Macleod of Leeds).

In treatment of wounds already septic hypochlorous acid (or eusol) would be much more popular if it could be obtained in a fresh state. This is how it can be done: calx chlorinata to the amount of 45 grains is rubbed smooth and put into 8 ounces of a 15 per cent. solution of sodium chloride. This may be kept for an indefinite period. When needed all one has to do is to add boric acid crystals, 45 grains or more, and one has eusol of full standard strength (or a little more) in a 15 per cent. solution of sodium chloride. But as a matter of fact one-third standard is quite strong enough for continued use so far as the eusol content is concerned, and 5 per cent. quite enough for hypertonic saline. So what one

does is to add, say, four ounces of the solution-suspension to twice the quantity of warm water, in which half, 45 grains of boric acid has already been dissolved. Shake up, stand for a few minutes, and decant. The boric acid can safely be guessed as to quantity, for excess of it does no harm. The new solution should have the characteristic fresh smell, and is admirable for irrigating septic wounds or septic or doubtful uteri.

For a flat septic surface or ulcer the solution-suspension is added to double the quantity of warm water, mixed well, and enough poured on to a warmed sterilized plate to soak thoroughly, neither more nor less, a piece of boric lint that will suitably cover the wound. Oiled silk must be put on over it, and if examined several hours later the hypochlorous acid gas can still be smelt. And all this time and much longer the hypertonic saline is maintaining its activity. It is of prime importance, of course, that the liquid should not at any stage be exposed to heat much above that of the body. I have used these methods for a good many years.

The boric lint method is admirable for septic burns, but after the first two applications it can generally be used considerably weaker.

Hypertonic saline solution is a very valuable dressing for ordinary burns, whether tanned or not, and I therefore suggest that hypochlorous acid in hypertonic saline solution is likely to prove a satisfactory dressing for the skin lesions of "mustard" gas.

—I am, etc.,

W. REGINALD WILSON, M.B., B.Ch.

Doncaster, Sept. 26.

Social Pathology

SIR.—I agree with Dr. A. J. Brock (October 8, p. 762) that the medical profession can supplement the lessons of past history by emphasizing the pathological analogies of social defects. Those who return to society no useful service for all the care and expense of their upbringing are like tumours which collectively may become malignant. Social organizations are analogous to the neurones of the central nervous system. Their leaders are "contactors" like the synapses, and the amount of authority given to these leaders (like the blood supply of the synapses) governs their activity and the resulting conduct of society (see article *Journal*, February 5, p. 265). Just as a septic focus near the carotid artery may cause pathological changes of the cerebral capillaries and thus mental disorder, so may evil influences upon those in authority eventually determine an anti-social state.—I am, etc.,

Birmingham, Oct. 10.

F. A. PICKWORTH.

The Services

DEATHS IN THE SERVICES

Lieutenant-Colonel PHANINDRA NATH BASU, I.M.S., died at Vienna on July 25, aged 48. He was born on October 31, 1889, and was educated at the Calcutta Medical College, where he graduated M.B. in 1913. He joined the Indian Medical Service as temporary lieutenant on July 17, 1917, and on November 1, 1920, received a permanent commission, being ranked as captain from July 17, 1920. He took the D.P.H.Eng. in 1923, and in 1924 the D.T.M. of the London Colleges and the M.R.C.P.Ed. He attained the rank of lieutenant-colonel on January 16, 1937. He served during the latter part of the war of 1914-18. He had been a member of the British Medical Association since 1921. He was professor of pathology at the Medical College, Madras, and had held the post of deputy assistant director of pathology for the Bombay District.

Obituary

SIR HENRY GRAY, K.B.E., C.B., C.M.G.,
LL.D., F.R.C.S.Ed.

Though fifteen years have passed since Sir Henry Gray left Aberdeen for Montreal, the news of his sudden death on October 6 caused almost as much grief and regret as if he had never left the place. Not surprising this to those who knew the man and his worth, for he was ever a live force, a lovable personality; a great surgeon, and an outstanding teacher of the principles and practice of his art. Add to these his devotion to the special training of men bent on surgery and his success in this direction as evidenced by the number of his distinguished pupils on our hospital staffs and others, and it will be understood that the recalling of his name and worth has been a constantly recurring event up to this time and I feel will long continue.

Henry Mellree Williamson Gray was born in 1870, his father, Mr. A. R. Gray, being a prominent business man in Aberdeen. Educated at Merehiston Castle School, Edinburgh, of which he was captain, he was from 1888 to 1891 in business with his father. In the latter year he entered Marischal College to study medicine, where he had a distinguished career,

graduating with honours in a strong year, among his contemporaries being the brilliant Arthur Lister, nephew of Lord Lister. A year spent as house-surgeon to Sir Alex. Ogston followed graduation, and here Gray found his sphere and grasped his opportunities, taking a greater interest than was usual in those days in the work of the "dressers" in the wards. In 1896, he proceeded to Germany, spending a year and a half in Bonn, Leipzig, and Berlin, studying mainly surgery and gynaecology. He left Aberdeen surgery gradually shedding some of the trappings of the antiseptic system and striving after a safe but simpler technique. He found German surgery far advanced in the development of the aseptic system, and when he returned to Aberdeen he had mastered this technique and brought much new equipment with him. He was the first here to start as a surgeon without a preliminary period in general practice. By some prominent members of the profession this was resented and for some years he had no easy row to hoe. But Gray never lacked courage and tenacity of purpose, and he pursued the even tenor of his way. After a short period as anaesthetist, and a few years as assistant surgeon at the Royal Infirmary, he got wards in 1904. A very strenuous time followed till the outbreak of war. A man of original mind, while he did his own thinking, he read widely and used his assistants to amplify his information from this source; he made frequent visits to the Continent, and from one of these brought back omnopon, with which he widened the field of local anaesthetic operation.

He was always striving after a more perfect technique, better and safer anaesthesia, and reduction of shock before, during, and after operation. One should not forget to

mention his interest in the "lost sheep" or the "forlorn hope"—the patient who had got the dreaded verdict elsewhere "too late—inoperable." To such of these as he thought had a chance and were prepared to make that choice his technique, resource, courage, patience, and physique often gave success. He considered the individual first, and the criticism of his daring that might and did follow failures in such cases affected him little, if at all. His attitude to such might be summed up in the motto of Marischal College—"They say. What say they? Let them say." He was beloved by his patients; he gained their confidence without effort, by obvious strength of body and character, his geniality and pawky humour and his forthright method, coupled with a sympathy which gave courage and cheer. He was human, however—"there are spots even on the sun"—his idealism in the surgical theatre was at times too high for the attainment of the luckless assistant who fell short of expectation, and sharp reproof rang out in no uncertain way. It rankled at times, but geniality was resumed with the casting of the operating garment and the closing of the theatre door behind him.

Gray was a patriot in no measured way. In 1899 he served as a civil surgeon in the South African War and was invalided with typhoid fever. In 1900 he was gazetted surgeon captain to the Aberdeen Volunteer Artillery, and later was a major (R.A.M.C.T.) *à la suite* in the 1st Scottish General Hospital. In 1914 he volunteered for service abroad and did not return to his practice till June, 1919. His first appointment in France was chief surgeon to the British Red Cross Hospital at Wimereux, with his fellow-student Arthur Lister in charge of the medical side. In November, 1914, he was appointed a consulting surgeon B.E.F. and was for a time in the Rouen area, and later was consulting surgeon to the 3rd Army. His keenness as a teacher was manifest in his willingness to operate and assist at operations for instructional purposes, and he did pioneer work in the treatment of wounds by excision and also in the treatment of head injuries. His technique in the latter case earned the warm approval of Harvey Cushing in a communication from France to the *B.M.J.* or *Lancet*. Having served in the forward area with every army on the Western Front, one was struck with the pains that Gray took to realize the conditions under which field ambulance officers and regimental medical officers worked. During the battle of Arras, on a "hard" day he was found near Monchy-le-Preux with gas-mask at the alert on a round of visits to dressing stations to see how they were going.

A gift he valued highly was a massive piece of silver plate inscribed with the signatures of some sixty surgeons who had served under him in France, in appreciation of his service for and with them. There is more than a touch of irony in the fact that among the signatures are a few Canadians, including Mr. Archibald, whom McGill University favoured in place of Gray, who was the choice of the Governors of the Royal Victoria Hospital, Montreal. With a complete knowledge of all the moves made by the Governors of the Royal Victoria Hospital to induce Gray to go to Montreal and the guarantees given before he accepted, combined with some reliable information from Canadian sources, it is difficult to restrain the Celtic side of one's personality in expressing one's views. Shortly, however, let us acknowledge that Gray had a "raw deal" in Montreal.

Gray was a great sportsman and played cricket in every sense of the word. He could make the ball do tricks on the ground and in the air long before spin and swerve

became common terms. He was keen with the gun and fishing rod, but to me he was at his best on the snow-clad hills around Braemar and Balmoral, in a five-days hind-stalking trip in the last week of December and in the long evenings spent in that famous hostel, the Fife Arms, Braemar. His hospitality was unbounded, and many residents, young graduates, and others will recall with pleasure Sunday evenings when 34, Albyn Place was an open house.

He paid a short visit to Aberdeen in 1927; at two days' notice some fifty old colleagues held a dinner in his honour. He was as of old—no bitterness, no rancour, no upbraiding—a great surgeon—a great gentleman.

Ave et Vale.

WILLIAM FLETCHER, M.D., F.R.C.P.

We regret to announce the death on September 18 at the age of 64 of Dr. William Fletcher, until recently Director of the Institute for Medical Research at Kuala Lumpur. Dr. Fletcher was educated at Caius College, Cambridge, and St. Mary's Hospital, where he gained a University scholarship in 1893. He qualified M.B., B.Ch. in 1896, proceeded to the M.D. in 1910, and in 1926 took the M.R.C.P. He was elected a Fellow of the Royal College of Physicians in 1933. Dr. Fletcher spent a few years in general practice at Coventry, and left this in 1903 to join the Government Medical Service in Malaya, where he acted as first medical officer to the General Hospital, Kuala Lumpur. In 1908 he was appointed pathologist to the Institute for Medical Research, where he worked, among others, with the late Sir Thomas Stanton, whom he finally succeeded as director. Dr. Fletcher was awarded the Craggs Prize in 1909 for his essay written in conjunction with Dr. Doris Mackinnon on beriberi. He was joint-author of a Medical Research Committee report on chronicity in dysentery carriers, and was well known for the work he had done on melioidosis. His publications on tsutsugamushi disease and on tropical typhus appeared in the *Transactions of the Royal Society of Tropical Medicine and Hygiene* in 1928 and 1929.

During the war Dr. Fletcher served as pathologist at the University War Hospital, Southampton, and except for this intermission he lived in Malaya for twenty years. When he left Malaya he became an active member of the Royal Society of Tropical Medicine, and also served as the secretary of the Colonial Medical Research Committee. He is survived by his widow and a son and a daughter.

Dr. A. Felix of the Lister Institute writes:

William Fletcher's work on typhus fever has gained for him an international reputation. In 1924, working at Kuala Lumpur in collaboration with J. E. Lesslar, he first recognized as typhus one of the continued fevers of the Malay States and called the disease "tropical typhus." In the following year Fletcher made the important discovery that there were two serological groups of tropical typhus, which could be distinguished by the agglutination reactions which the serum from the patients gave with two different strains of *Proteus X*. The two groups were later shown to have a different distribution and were referred to as shop typhus (urban group) and scrub typhus (rural group). Fletcher's observations at first appeared to be very puzzling. His work, however, has not only been fully confirmed and amplified so far as the tropical typhus of the Far East and the Japanese river fever (tsutsugamushi) are concerned: it also has had a most stimulating effect on the study of typhus-like

fevers that occur in different parts of the world. A number of diseases previously described as "unclassified fevers" that occur in various tropical and subtropical countries have been studied on similar lines and recognized as members of the "typhus group of fevers." Fletcher's work on the two serological types of tropical typhus will, therefore, mark a turning point in the history of typhus research. Fletcher was a man of quite exceptional charm. He will be remembered not only by those who were privileged by his personal friendship but also by many British and foreign bacteriologists to whom he extended his ever-ready help or advice.

E. COLLINGWOOD ANDREWS, M.D.

We regret to announce the death on October 7 of Dr. Edward Collingwood Andrews of Hampstead. Dr. Andrews was born in 1862 in London, being a son of the late Dr. James Andrews, who practised at first in the Camden Road and later in Hampstead. Collingwood Andrews was educated at University College School, and from there went up to St. John's College, Cambridge, where he matriculated in 1880 and obtained a scholarship in natural science; he took the B.Sc. degree at London University in 1882 and his B.A. at Cambridge in 1884. The M.R.C.S. he obtained in 1885, the M.B., B.Ch. Cantab in 1886 and the M.D. Cantab in 1892. After holding a resident obstetric appointment at Guy's Hospital he joined his father in practice at Hampstead.

At an early period in his career Andrews began to take interest both in the public life and in the professional work of the district. As surgeon to the Hampstead General Hospital in its early days when it was staffed by general practitioners he took his full share of the work, and he then enjoyed the full confidence of his colleagues in his judgment and in his skill as an operating surgeon. When the National Insurance Bill was being discussed he was in strong opposition to it; but when it became law circumstances were such that he, like many others, was compelled to accept it. Later in life he was called upon by the Ministry of Health to serve upon Courts of Referees in appeals under the National Health Insurance Acts, a very high opinion of his capacity as an adjudicator being held by the authorities. He was a well-known figure in the public life of the Borough of Hampstead: he served in the 19th Middlesex Rifle Volunteers; he was one of the original members of the borough council when it was first formed in 1900, and his years of service upon it amounted in all to twenty-five. During this time Andrews was elected an alderman on two separate occasions and he was appointed mayor in November, 1903, and again in 1926 and 1927. His services to the borough were considered to be of such outstanding merit that the council elected him a Freeman in 1935.

Collingwood Andrews was a courteous and a kindly man; he was popular with his colleagues and his patients; he was a man who weighed evidence and formed his own opinion. When these attributes are found together with knowledge and a judicial mind we have that combination which goes to make the best type of general practitioner and a citizen of no small worth to the community in which he lives. His opinion always carried weight whether it was on the council of his old school or on the borough council. So his life, full of service to his fellow-men, is ended, and his death will be mourned by numbers of friends, patients, and colleagues. Andrews was twice married and is survived by his widow and two sons; his elder son succeeds him in the practice founded by the grandfather.

J. E. W. MACFALL, M.D.

Professor of Forensic Medicine, University of Liverpool

Professor J. E. Whitley MacFall, whose death at the age of 65 on September 30 we record with regret, was an outstanding member of the considerable group of Liverpool students who have attained eminence in their own medical school. He qualified M.B., Ch.B. in the old Victoria University, becoming M.D. Liverpool shortly after the inauguration of the new University. He also became a member of the Inner Temple, and early took a deep interest in medical jurisprudence. After assisting the late Professor R. J. M. Buchanan for a number of years as lecturer and demonstrator, he succeeded him on his death in the chair of forensic medicine and toxicology in the University of Liverpool. MacFall also undertook the editorship of Professor Buchanan's well-known textbook, and prepared and enlarged the ninth edition, issued after the latter's death. He was a man of industrious and conscientious habits, never sparing himself in his careful consideration for the welfare of his patients, always displaying the most accurate attention to detail in the study of medico-legal problems. His conspicuous success in the solution of such problems was due no doubt to the fact that he continued in private practice even when the medico-legal work must have demanded the major part of his time and thought; this ensured the maintenance of a broad outlook, based as it was on clinical experience as well as on laboratory investigations. He served in France in the great war in command of the 3/1st West Lancashire Field Ambulance, 1914-18, and sustained a gunshot wound, from which he made a complete recovery. MacFall's wide reputation led to his extensive employment in the investigation of crime; he became a well-known expert witness in the law courts of his native city as well as further afield. He also acted as examiner of medical students in several of the universities of Great Britain. At the Annual Meeting of the British Medical Association in Edinburgh in 1927 he was honorary secretary of the Section of Forensic Medicine.

Professor MacFall was not an easy man to know intimately, but he had a circle of close friends who appreciated his sterling qualities and will sadly miss his enthusiastic and forceful personality. A tall man of athletic build, he was a familiar figure on horseback on the Mersey sands to the north of Liverpool, the first item of his Sunday routine—a ride, a game of tennis, a swim, and a game of chess—a routine which he practised beyond the age of 60. He was married twice, and he leaves a widow, and one son and two daughters by his first marriage.

THE LATE DR. HESTER DILL SMITH

Lieutenant-Colonel A. E. J. Lister, I.M.S. (ret.), late Professor of Ophthalmology, King George's Medical College, Lucknow, writes:

I would like, on behalf of myself and many other officers of the I.M.S., to pay a tribute to the memory of the late Mrs. Hester Dill Smith, M.D., of whose death a sympathetic memoir appears in the *Journal* of October 1. I and many others owe her a debt of gratitude for her kindness, encouragement, and hospitality which we can never forget.

This is not the place to attempt in any way to assess the value of the work of her husband, Lieutenant-Colonel H. Smith, C.I.E., I.M.S. (ret.). When the final history of the intracapsular extraction of cataract is written and the fires of controversy have died out, posterity will assign to him his rightful place, and it will be no insignificant one. Few, however, beyond Smith himself and a few intimate friends know how much he owed to the sympathy and practical help of his wife. It was over thirty years ago that I first met Mrs. Smith at Jullundur. To me, as

to scores of others who arrived in Jullundur profoundly sceptical as to the value of Smith's operation, her attitude was, put briefly, "Come and see it, examine the results, and judge for yourselves." This also meant to scores of visitors, as to myself, "Come and stay in my house, as my guest, for as long as you like."

It involved no small amount of trouble and expense, and this at a time when Smith had a family to educate and no great excess of worldly wealth. She, however, profoundly believed in his work, and wanted others to see it, first hand, and judge for themselves. No one who was privileged to be her guest can ever forget her charming smile of welcome, her interesting talk and shrewd observations, and her personal interest in his own particular work. She was very highly endowed intellectually, and had made good in her own sphere of work before she married. Though for the sake of her family she gave up her own professional career, no one who knew her can doubt that, had she not done so, she would have made a name for herself. She had a genius for friendship, and kept in touch with some of her husband's pupils until the end of her life. Her passing has left a gap in the lives of those who knew her well which will never be filled, and their profound sympathy goes out to her husband and her two sons.

Universities and Colleges

UNIVERSITY OF LONDON

The University of London Library, formerly at South Kensington, has been removed to its new building at Bloomsbury. In future all communications should be addressed to the Goldsmiths' Librarian, University of London Library, Bloomsbury, W.C.1.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN PUBLIC HEALTH.—S. N. Chelliah, A. L. St. A. McClosky, A. B. Xuma.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examination indicated:

DIPLOMA IN PUBLIC HEALTH.—S. Ball, A. Cathcart, D. H. Williams.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

The Bradshaw Lecture on "The Chemotherapy of Bacterial Infections" will be delivered by Dr. Lionel Whitby at the College, Pall Mall East, S.W., on Thursday, November 3, at 5 p.m., and the Fitzpatrick Lectures by Dr. Harold Scott on "Conquest of Diseases in the Tropics" on Tuesday and Thursday, November 8 and 10, at 5 p.m. Any member of the medical profession will be admitted to the lectures on presentation of card.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The autumn course of museum demonstrations in the theatre of the College commences on Monday, October 17. On that date and on October 24 Mr. L. W. Proger will demonstrate new pathological specimens in the museum. Dr. A. J. E. Cave will discuss the anatomy of the mammary gland on October 21; the anatomy of the female reproductive organs on October 28; and the anatomy of the male reproductive organs on November 4. On October 31 Mr. R. Davies-Colley will demonstrate tumours of the kidneys. All the demonstrations commence at 5 p.m., and are open to advanced students and medical practitioners.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, held on October 3, with Dr. John Henderson, the President, in the chair, the following were admitted Fellows of Faculty: James Henderson Levack, M.B., Bhutnath Raylahiri, M.B., Eliza Moira Kennedy Stevenson, M.D.

Medical News

The Medical Research Council has appointed Sir Henry Bashford, M.D. (Chief Medical Officer of the General Post Office), and Sir Kenneth Lee, LL.D. (chairman of Tootal Broadhurst Lee Co., Ltd.), to fill vacancies in the membership of its Industrial Health Research Board.

The Eugenics Society announces lectures by Dr. J. A. Fraser Roberts on "Intelligence and Family Size," Professor C. Spearman on "Intelligence Tests," and Mr. R. S. Walshaw on "External Migration," to be given at Burlington House, Piccadilly, W.1, on Tuesdays, October 18, November 15, and December 20, respectively, at 5.15 p.m.

On Tuesday, October 18, at 1.25 p.m., at the Church of St. Stephen, Walbrook, close to the Mansion House, Mr. W. McAdam Eccles will give an address on St. Luke. The offertory will be devoted to the Royal Medical Benevolent Fund.

Lord Horder will open the Finsbury Health Centre, Pine Street, E.C., on Friday, October 21, at 4.30 p.m.

"The Physiology of the Vocal Mechanism" will be the subject of the annual address to be given by Mr. Douglas Guthrie at the Central London Throat, Nose and Ear Hospital, Gray's Inn Road, W.C.1, on Friday, October 21, at 4 p.m.

A sessional meeting of the Royal Sanitary Institute will be held in the Royal Pavilion, Brighton, on Friday, October 21, at 5 p.m., when discussions will take place on "School Exclusion in Infectious Disease," to be opened by Dr. Duncan Forbes, and on "The Repair of Working-class Dwelling Houses," to be opened by Mr. A. Howard Holt.

The annual general meeting of the Society of Physiotherapists will be held at the Langham Hotel, W., on Saturday, October 22, at 2.30 p.m. At 3.45 p.m. there will be an "At Home" at which Dr. E. P. Cumberbatch will speak on "Short-wave Treatment."

A lecture on "The Anaesthetist and his Apparatus" by Dr. Victor Goldman, arranged by the Institute of British Technicians (6, Holborn Viaduct, E.C.1), will be given at the Welbeck Hotel, Welbeck Street, W., to-day (Friday, October 14), at 8.15 p.m. Tickets will be issued free to members of the medical profession on application to the secretary of the institute.

A dinner in celebration of the twenty-first anniversary of the Medical Women's Federation will be held at the Criterion Restaurant, Piccadilly Circus, W., on Saturday, October 29, at 7.15 for 7.30 p.m. It will be followed by the presentation by members of the Manchester and District Association of a short play by Dr. Mary Sheridan. The dinner will be attended by medical women only, and non-members will be welcome. Tickets, price 10s. 6d., exclusive of wines, should be obtained without delay from the office of the Medical Women's Federation, 9, Clifford Street, Bond Street, W.1.

Dr. P. del Rio-Hortega will give two lectures on "The Histology of the Nervous System" at the Nuffield Institute for Medical Research, Woodstock Road, Oxford, on Wednesdays, November 2 and 9, at 8.45 p.m.

The South-West London Medical Society will hold the following meetings during the next five months: October 19, Dr. D. Evan Bedford, "Functional or Organic?—Difficulties in the Diagnosis of Heart Disease." November 9, Mr. Laurence O'Shaughnessy, "Indications for Cardiac Surgery." December 14, Mr. Gavin Livingstone, "An American Interlude." January 11, Dr. E. ff. Creed, "Laboratory Diagnosis as a Guide to Treatment." February 8, Mr. Leonard Phillips, "Pelvic Disproportion." The meetings are to be held at the Bolingbroke Hospital, Wandsworth Common, S.W., on Wednesdays at 9 p.m.

An exhibition by the Medical Art Society is now open at the Rembrandt Gallery, 5, Vigo Street, London, W.1, and will close on October 29.

The following programme for 1938-9 has been arranged by the Hunterian Society: October 17, 7.15 p.m., at Simpson's Restaurant, Cheapside, E.C., presidential address by Mr. Andrew McAllister, "The Influence of the Hunterian Era on Modern Obstetrics." November 7, 9 p.m., at Apothecaries' Hall, Water Lane, discussion: "That Psychological Treatment of the Criminal is Preferable to Punishment of the Crime," to be opened by Mr. St. John Hutchinson, K.C., Dr. H. Yellowlees, Mr. Albert Lieck, and Sir Holman Gregory, K.C. December 19, 7.15 p.m., at Simpson's Restaurant, E.C., discussion: "Sneezing," to be opened by Dr. George Riddoch, Mr. C. Hamblen-Thomas, and Dr. George Bray. January 16, 9 p.m., at Mansion House, E.C., Hunterian Lecture by Professor Emil de Grosz of Budapest, "The Problem of Glaucoma." February 9, 7.30 p.m., annual dinner at May Fair Hotel. February 27, 9 p.m., at Mansion House, Hunterian Oration by Mr. Cedric Lane-Roberts, "A Plea for the Woman in Gynaecology and Obstetrics." March 20, 7.15 p.m., at Simpson's Restaurant, E.C., discussion: "Misleading Leading Symptoms," to be opened by Lord Horder and Mr. W. H. Ogilvie. April 17, 7.15 p.m., annual general meeting, followed by lecture by Dr. C. Ainsworth Mitchell, "Identifications in Criminology."

The Minister of Health has appointed Dr. Albert Edward Quine, a Medical Officer of the Ministry, to undertake the duties of Inspector of Anatomy in England and Wales.

The Board of Control, with the approval of the Minister of Health, has appointed Dr. R. G. Anderson to be a Commissioner to fill the vacancy caused by the retirement of Surgeon Rear-Admiral J. Falconer Hall, C.M.G., R.N. (ret.).

Dr. Rufus Cole, director of the Hospital of the Rockefeller Institute since 1909, received the George M. Kober Medal for distinguished service to medicine from the Association of American Physicians at its annual meeting.

EPIDEMIOLOGICAL NOTES*

Acute Poliomyelitis

The incidence of acute poliomyelitis in England and Wales continues to decline, 56 cases being notified during the week under review, compared with 60 in the previous week; in London the figure remains at 3, but in Scotland a drop from 10 to 5 was recorded. The counties mainly affected were: Staffordshire 5, 4 each in Carmarthen, Essex, and Sussex West, and 3 each in Suffolk West, Yorkshire East Riding, and Yorkshire North Riding. More than one case was reported from the following centres: Horsham 4, London 3 (Battersea, Holborn, and Wandsworth), 2 each in Birmingham, Carmarthen, Cannock, Cosford (Suffolk), and York. In Essex and Suffolk fresh cases continue to be notified at intervals: in addition to those mentioned, single cases were notified in Braintree, Saffron Walden, and Sudbury (Suffolk). The outbreak in Carmarthen continues, the areas affected being Carmarthen 2, Llanelly 1, Carmarthen rural 1. Although no fresh cases were reported in Llandilo rural district for the week, there have been 5 cases altogether, 4 of them confined to a small area in Salem, with 1 death. The Horsham cases occurred at an interval of nearly four weeks from the last case notified.

A decline in the prevalence of acute poliomyelitis has been reported from the Continental countries in which the disease has been epidemic. During the week ended September 17 in Germany the number notified declined from 419 to 386; the chief centres were: district of Cologne 80 (97), district of Düsseldorf 19 (27), district of Wiesbaden 27 (29), district of Frankfurt 15 (9), Württemberg 55 (72), Baden 16 (13), Saar 13 (17), Saxony 33 (33), and Bavaria 50 (33). During the same week in Austria there were 18 (39) cases. In the week following in Holland notifications fell from 54 to 30, of which 6 were in the Province of South Holland. France has been relatively free from the disease: during the whole of August only 81 cases were notified, distributed over thirty-

two departments, chiefly in: the Department of the Rhône 12, 6 each in the Departments of the Seine, Bas-Rhin, and Côte d'Or, 5 in the Ain Department, and 4 each in the Departments of the Isère and Haut-Rhin.

Primary and Influenzal Pneumonia

The increase in the incidence of pneumonia (primary and influenzal) in England and Wales referred to last week has not been maintained, the number of cases notified having fallen to practically the same level as in the previous week. Of the 16 deaths in the 126 Great Towns there were 3 in Liverpool and 2 in Southport.

Diphtheria and Scarlet-Fever

There was a slight increase in the notifications of diphtheria in England and Wales during the week—1,209, compared with 1,198 in the previous week—but in London a decrease was reported (from 152 to 129). The chief centres affected were: Plymouth 12 (9), South Shields 18 (13), Manchester 27 (19), Leicester 24 (14), Cannock 11 (1), Birmingham 35 (24), Carmarthen 5 (1), Cardiff 14 (7). In Scotland a small drop was recorded: Glasgow 70 (65), Edinburgh 21 (17), West Lothian County 11 (4), Lanark 10 (12), Renfrew 8 (11). Of the 30 deaths in the 126 Great Towns of England and Wales 3 each occurred in London, Leicester, and Liverpool, and 2 each in Birmingham and South Shields. There has been no abatement of the outbreak in South Shields, where there have been 365 cases to date this year with 54 deaths: notifications for the last four weeks were 15, 16, 13, and 18 respectively, and for the same periods 0, 2, 3, and 2 deaths respectively were recorded. A campaign by the public health authorities for immunizing the population at risk against the disease has met with a good response, but from the nature of things immediate results cannot be expected. Four deaths from diphtheria were recorded in Glasgow and 1 each in Edinburgh and Paisley.

Further increases in the incidence of scarlet fever were recorded in England and Wales and in Scotland, but in London there was a drop from 160 to 155 in the week under review. The chief increases were reported from: Stockport 10 (6), Poole 8 (5), South Shields 16 (7), Stockton-on-Tees 9 (6), West Ham 22 (15), Barnet 8 (0), Gillingham 8 (1), Bootle (Lancs) 17 (6), Liverpool 46 (43), Manchester 34 (23), Nottingham 31 (26), Croydon 7 (4), Sheffield 35 (18). During the week only one death (at Twickenham) was recorded in the 126 Great Towns. There were no deaths from scarlet fever in Scotland or Ireland.

Measles and Whooping-cough

Three deaths from measles (1 each in Kingston-upon-Hull, Sunderland, and Stoke-on-Trent) were recorded in the 126 Great Towns of England and Wales, compared with 2 in the previous week. In Scotland the notifications fell from 18 to 13 in the week under review, the chief centres being Glasgow 6 (4), Kirkcaldy 2 (1), and Lanark 2 (2). Of the 10 deaths from whooping-cough in the 126 Great Towns, 1 each occurred in London, Hastings, Bootle, Huddersfield, Kingston-upon-Hull, Liverpool, Birmingham, Nottingham, Norwich, and Swansea. In Scotland there was an appreciable drop in the notifications of whooping-cough—94, compared with 125 in the previous week. Three deaths were recorded (2 in Glasgow and 1 in Aberdeen).

Cholera: Plague

During the week under review 113 cases of cholera and 38 deaths were recorded at Shanghai, while in Eastern Kwangtung during the week ended September 17 there were 526 cases and 116 deaths. During the week ended October 1, 3,463 cases of cholera and 1,526 deaths were recorded in the Central Provinces of India and 237 (211) cases and 122 (93) deaths in the United Provinces.

In India during the week ended October 1 there were further increases in the incidence of plague: Central Provinces 166 (116) cases and 7 (6) deaths; Madras 35 (18) cases and 15 (15) deaths; Bombay 21 (14) cases and 20 (14) deaths.

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended October 1, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns (124 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

| Disease | 1938 | | | | | 1937 (Corresponding Week) | | | | | 1929-37 (Median Value Corresponding Weeks) | |

* After October 1, 1937, puerperal fever was made notifiable only in the administrative county of London.

† Deaths from puerperal sepsis.

‡ Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, Aitology Westcent, London.

SECRETARY, Medisecra Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúirí na h-Eiréann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: Bacillus, Dublin; telephone 62550 Dublin).

QUERIES AND ANSWERS

Infrequent Menstruation

"W. A. C." writes: A girl aged 17 complains that her periods since their commencement three years ago have appeared only once every three months. She complains also of offensive leucorrhoea at about the times when her periods might have been expected if they were more normal. She has a marked growth of hair on the upper lip. She worries, and is anxious for treatment. What can be done for her?

Treatment of Buccal Ulcers

Surgeon Lieutenant-Commander J. C. GENT writes with reference to Dr. R. E. Isaac's letter (*Journal*, October 1, p. 727): I suggest treatment along the following lines: (1) dry the ulcers with cotton-wool; (2) apply 8 per cent. zinc chloride for one minute; and (3) paint with Talbot's solution (zinc iodide, 110 grains; distilled water, 82 minims; iodine crystals, 183 grains; glycerin to 1 oz.). This procedure is advised in Hutchison's *Index of Treatment*. I had occasion to try it last year in the case of my own father, then a man of 75, who had suffered from buccal ulcers for about five years. It appeared to give him more relief than any other treatment which had been tried, although the condition never recovered completely.

Dr. R. HERSON writes in answer to Dr. R. E. Isaac's inquiry: I would advise that the buccal ulcers be painted with 1 per cent. aqueous gentian-violet twice a day.

Treatment of Pruritus Ani

Dr. W. A. MARRIS (Birmingham) writes: "J. M." will find he can give his patient prompt relief by dusting the anal folds with calomel undiluted by any other powder. Direct the patient to smooth a pinch of the powder into the folds round the anus on going to bed. Two drachms is sufficient for relief, but relapses will occur after months. I mentioned this treatment to a skin specialist, and the next time we met he thanked me for the tip.

r. J. JONES (Kinnel Bay, Rhyl), as one who has suffered from this distressing malady, and who cannot even now claim to be absolutely free from it, writes: I attribute my greatly improved condition to the following lines of treatment: (1) a course of x-ray therapy at the hands of a capable radiologist; (2) the use of anusol suppositories, which contain bismuth oxygallate, zinc oxide, balsam of peru, etc. (William R. Warner and Co. Ltd.); and more recently (3) to the use of "nohaesa" suppositories and ointment, which may be obtained from Homburg Pharma Ltd., Africa House, Kingsway, London, W.C.2, and contain

camphor-chloral-menthol, together with camomile extract and calcium chloride. They are sedative in action and impart a grateful sensation of coolness to the affected parts.

"R.A.M.C.T." writes: At the end of the war, travelling homewards in a miserable little steamer, I contracted an acute condition of pruritus ani. After perhaps six weeks of exudative eczema and great discomfort I adopted the plan of sitting in a hip-bath of warm sodium bicarbonate solution every two waking hours for twenty minutes at a time. I was completely and permanently cured within three days. A friend with the same trouble followed my advice with the same happy result.

LETTERS, NOTES, ETC.

Medical Golf

The Medical Golfing Society held its autumn meeting on the Royal Cinque Ports Golf Links on October 1 and 2. The attendance was smaller than usual owing to the political situation, but a most enjoyable week-end was spent, with the following results. Bogey singles: Mr. L. G. Brown, 3 up (12). Foursomes: Sir Harold Gillies and Mr. John Everidge, after a tie with Dr. W. Dale and Dr. S. Pope at 1 down. Canny Ryall Cup: (1) Dr. S. Pope 86-12=74; (2) Mr. F. McG. Loughnane 89-14=75; (3) Dr. J. J. N. Daniels 93-15=78.

Disclaimers

Dr. DENNIS EMBLETON writes: A sensational article recently appeared in a London daily newspaper in which my name was mentioned. It referred to a paper by me on the dietetic treatment of diabetes which was published in the *Proceedings of the Royal Society of Medicine*. The newspaper article condemned the use of insulin, and was couched in such terms that it has evidently led many diabetics to believe that insulin is no longer necessary. During the last two or three weeks I have been bombarded with letters from diabetics, as have others engaged in this work. The remarks in the letters range from the pathetic request that the "new treatment" should be given, to downright abuse at having been subjected to the "torture of the syringe" for so many years. As can be seen on reference to the original paper, no such claim was made by me. My paper was a plea for the more extensive use of diet in the treatment of diabetics over the age of 40. The complete withholding of insulin in all cases was never suggested; such a procedure would be obviously dangerous, particularly in diabetics of the young age group.

Sir HAROLD WERNHER, Chairman of the Voluntary Hospitals Emergency Bed Service, writes from 10, Old Jewry, E.C.2: In the broadcast which took place in the London Regional News at 10 o'clock on Friday last concerning this Service the B.B.C. wished to give a realistic impression of how the work is carried out. In order to do this they broadcast the Emergency Bed Service end of an actual conversation with a doctor. Unfortunately, and quite unintentionally, the name of the doctor was also broadcast. I need hardly say that it was never intended that this should occur. On behalf of the doctor in question I should like to make it clear that he was in no way aware that his name would be broadcast, and would certainly not have given his permission for it had he known.

Corrigendum

Dr. WILLIAM BROWN, Director of the Oxford University Institute of Experimental Psychology, writes: On page 770 of the *Journal* of October 8 there appears a paragraph about psychology at Oxford which is quite incorrect. It was in 1936 that the Institute of Experimental Psychology was founded at Oxford with the help of Rockefeller grants and, in particular, with the help of a generous gift of £10,000 from my friend Mrs. Hugh Watts. The event is described in my article on "Psychology at Oxford," published in the *British Medical Journal* of May 30, 1936—although at that time Mrs. Hugh Watts preferred to be anonymous. At a private dinner which my wife and I gave in Christ Church Hall on July 31 of this year, during the meeting of the tenth International Medical Congress for Psychotherapy, to about seventy people, including delegates of the Congress, in honour of the president, Professor C. G. Jung, Mrs. Hugh Watts was the other principal guest. I explained in a short speech at the end of the dinner the circumstances in which her generous gift was made to the University when the Institute of Experimental Psychology was founded in 1936.

KEY TO CURRENT MEDICAL LITERATURE

GENERAL JOURNALS

Deutsche Medizinische Wochenschrift

Berlin vol. 64 July 29, 1938

- Chemotherapy of Gonorrhoea. B. Spiehoff.—p. 1097.

Present Position of Anti-malarial Drug Therapy in India. R. N. Chopra.—p. 418.
Early Ophthalmologists in Calcutta. E. O'G. Kirwan.—p. 423.

Solu-septasine in Simian Malaria.—The destructive effect of solu-septasine on the *Plasmodium knowlesi* in rhesus monkeys appears to be exceedingly powerful. One injection was sufficient to check a very severe infection, and after a second the parasites disappeared altogether from the peripheral circulation. The sulphonamide compounds appear to be effective specific drugs in malaria.

Presse Médicale

Paris vol. 46 July 27, 1938

- *Lumbo-sacral Sympathectomy in Diabetic Arteritis of Lower Limbs. H. Chabautier, P. Gaume, and C. Lobo-Onell.—p. 1161.
Cerebrinspinal Circulation, with Special Reference to Effects of Centrifugal Force on this System and on General Circulation in Airmen. F. Pedrazzini.—p. 1164.

Sympathectomy for Diabetic Arteritis.—The authors describe the results of lumbo-sacral sympathectomy in seven cases of diabetic arteritis, some with advanced symptoms of gangrene. All were immediately and greatly improved by the operation, but unfortunately two died from other causes, one owing to an overdose of insulin and the other of collapse thirty-six hours after the operation. The five survivors remain greatly improved; pain which disappeared at the time of operation, has not recurred and the circulation is very much improved.

Syndrome of Hyperfolliculism: Its Limitations and its Anatomical and Clinical Bases. J. Vaugeois.—p. 1180.

Adaptability of *B. tuberculosis*.—As a result of forty-three years' work the author claims to have proved the existence of a "cyclic polymorphism" in *B. tuberculosis*—that is, under certain conditions it may assume the form of: (1) "cyanophile" germinative dust; (2) cyanophile granules; (3) cyanophile bacilli (non-acid-fast); and (4) typical acid-fast bacilli. He also claims to have shown that *B. tuberculosis* possesses a diffusible toxin which is killed by heating from 60° to 70° C.; that tuberculin is a thermostable and sensitizing toxalbumin produced by acid-fast bacilli; and that tuberculin treatment is essentially a form of shock therapy. The author has perfected a method of vaccine treatment derived from pure cultures of granular bacilli with which he has obtained considerable success in both non-pulmonary tuberculosis and in surgical tuberculosis with associated pulmonary lesions.

 Hyperglycaemia of Transitory Type and Glycosuria following Infarct of Myocardium (Fr.). S. Eckerström—p. 528.

Hypopituitarism.—X-ray investigation revealed a large sella turcica in five out of eight cases with a pituitary syndrome, the sella turcica being small in the remaining three cases. The syndrome in the first group is probably due to a chromophobe adenoma. The early stages and disguised forms of the complaint are described. Chronic headache with a high cerebrospinal fluid pressure and bitemporal hemianopia are characteristic, and are best treated by methods which aim at reducing the cerebrospinal fluid pressure.

 Full-term Abdominal Pregnancy with Recovery of Both Mother and Baby. W. D. Crecca and R. A. Cacciarelli—p. 312.

Artificial Fever and Sulphanilamide Therapy.—A very large number of cases of gonococcal infection of the female genital tract were treated either with sulphanilamide preparations or by means of artificial fever therapy. The majority reacted well to the former treatment alone, but when this failed to clear up the condition completely a combination of the two methods was often successful.

 Housing and Health. R. H. Britten—p. 957.

Chloramine Treatment of Sea Water.—The subject is discussed in relation to treatment of sea water for swimming-baths. Raw sea water alone kills 80 per cent of fresh sewage organisms in thirty minutes. With chlorination or ammonia chlorination over 99 per cent are killed in fifteen minutes. Pre-ammoniation to the extent of a quarter to one-half of the dose of chlorine dissipates two-thirds of the chlorine in ten minutes. The function of the residual chlorine as a disinfectant is discussed. With low chlorine doses, relatively higher mean residuals may be maintained in polluted sea water with the aid of ammonium compounds.

 *Antirabic Vaccination at Pasteur Institute in 1937. L. Crivellier and C. Viala.—p. 661.

Antirabic Vaccination.—The number of persons receiving antirabic treatment in France during 1937 was 454. There were no deaths and only one case of paralysis, which recovered. Particulars are given of the circumstances of the presumed infection demanding treatment (species of animal, situation and depth of bites, etc.), and of the geographical distribution of cases; a large proportion occurred in the neighbourhood of Paris. The cord suspension used on January 1, 1938, represented the 1,590th passage of the strain which has been used at the Pasteur Institute since its foundation.

 "Aniline Tumours" of Bladder. W. C. Hueper.—p. 856

Cytology and pH of Exudates.—It has been asserted by Menkin that a relationship exists between the hydrogen-ion concentration and the cytology of inflammatory exudates, alkalinity evoking a polynuclear response and acidity the advent of macrophages. These pH determinations were made colorimetrically, a method subject in this connexion to various errors. Steinberg and Dietz have studied the pH of peritoneal fluids by means of an electric potentiometer, glass electrodes

being introduced into the peritoneal cavity itself, peritonitis having been produced by the previous injection of bacteria. There was no apparent relationship between the pH of the exudate and its cytological characters, nor did it vary in any constant fashion with the nature or duration of the infection. The limits within which the pH varied were actually wider in normal peritoneal fluid than in the inflammatory exudates.

- *Demonstration of Lesions and Virus in Lungs of Mice receiving Large Intraperitoneal Inoculations of Epidemic Influenza Virus—E. R. Rickard and T. Francis, jun—p. 953.

Kupffer Cells and Vaccinia Virus.—Kupffer cells which have phagocytized iron oxide can be removed from liver perfusion fluid with an electro-magnet, washed free of other cells, and maintained for many days in culture. When vaccinia virus is mixed with these cells its *in vitro* activity is greatly reduced. When, on the other hand, virus is added to a culture of the cells *in vitro* it multiplies. No antiviral substance is produced by the living cells *in vitro*, and experiments are cited in which cultures of reticulo-endothelial cells failed to produce antibodies of other kinds. Hence tissue culture methods do not support the belief that the reticulo-endothelial system is responsible for antibody production, but this may be the fault of the method, by which the cells are deprived of resources available to them in the body.

Absorption of Vitamin K.—It is already recognized that a bleeding tendency associated with a low plasma prothrombin may be due to a deficiency of vitamin K (the anti-haemorrhagic vitamin). The bleeding tendency in dogs with a biliary fistula, which is also accompanied by a fall in prothrombin, is shown in this paper to be due to a deficient absorption of vitamin K; this can be corrected by the feeding of bile.

Intraperitoneal Influenza Virus.—A dose of influenza virus from 50,000 to 1,000,000 times greater than one which is fatal when given by the intranasal route to mice never causes death when injected into the peritoneal cavity. Lesions of moderate extent are produced in the lungs, and complete immunity to intranasal infection develops at an early stage.

Cl. welchii Toxaemia in Peritonitis.—Of twenty dogs immunized with repeated injections of *Cl. welchii* toxoid, and then given general peritonitis by an operation which deprived the appendix of its blood supply, followed by a large dose of castor oil, thirteen survived. Animals not so immunized but otherwise identically treated had previously shown a mortality of 91 per cent. It is also stated that *Cl. welchii*

antitoxin reduces this mortality, that the exudate in human peritonitis complicating appendicitis often contains *Cl. welchii*, and that antitoxin can be found in the blood of such cases after recovery; the authority given for these three statements consists of three papers still in the press. The views and works of earlier participants in the controversy over the supposed activity of *Cl. welchii* in peritonitis are not discussed.

Nutritive Value of Cereal Proteins.—The nutritive values of three cereal breakfast foods—a wheat endosperm product, a "whole-wheat" product, and pre-cooked rolled oats—were studied in human subjects by a milk-replacement method. The milk-replacement values of the proteins of the rolled oats and of the "whole wheat" were the same as their biological values; that of the wheat endosperm was higher than its biological value. Digestibility of the endosperm product was higher than that of the other two foods.

Egg-replacement Value of Proteins.—From an investigation by the protein-replacement method it was concluded that egg protein is superior to milk protein in maintaining the nitrogen balance in human adults. Powdered milk, fresh milk, and wheat endosperm with a small amount of cream added replaced egg nitrogen about equally well. Yeast used as a source of protein caused an increased negative nitrogen balance and an increase in total faecal solids without an increase in urinary nitrogen. The proteins of egg and of milk were equally well assimilated by human subjects. Similar results were obtained with rats.

Toxicity of Vitamin A.—The authors find that vitamin A is toxic for rats only in doses in excess of 100,000 international units per day. The greater part of such large doses is destroyed in the body of the rat. Vitamin B₁₂ did not counteract the toxicity of vitamin A; vitamin D did so only

partially; and ascorbic acid in doses of 5 mg. per day counteracted it almost completely. Fish oils contain, besides vitamin A, a toxic principle not yet identified.

Production of Microcytic Hypochromic Anaemia in Puppies on Synthetic Diet Deficient in Rat Anti-dermatitis Factor (Vitamin B₂). P. J. Fouts, O. M. Helmer, S. Lepkovsky, and T. H. Jukes.—p. 197.

Egg and Milk Proteins.—The biological value of egg protein was determined in adult human subjects and compared with that of milk proteins in the same subjects. The proteins of egg and of milk were equally well utilized, and egg protein was only slightly superior to milk in replacing nitrogen when the protein supplied 3 to 4 per cent. of the caloric requirements. The results were compared with those obtained with rats.

Canine Black-tongue.—By producing repeated attacks of black-tongue in dogs it was possible to compare the therapeutic effects of various products derived from liver. Simple aqueous extracts cured the condition; extracts prepared for parenteral use in the treatment of pernicious anaemia and the residues obtained at the same time were only partially successful even in huge doses, but when used together either extract or residue could replace the other. The results suggest that two substances partially separated by fractionation are present in liver, and are both necessary for the elaboration of some compound capable of curing experimental black-tongue in dogs and pellagra in man.

Nicotinic Acid and Vitamin B₆.—Nicotinic acid cured black-tongue in dogs, but failed to cure the dermatitis in rats and chicks produced by vitamin-B-deficient diets. It is concluded therefore that the rat dermatitis factor (vitamin B₆) and the chick dermatitis factor ("filtration factor") are distinct from nicotinic acid. Hence the vitamin B₂ complex contains four recognized entities: riboflavin (growth factor), nicotinic acid (curing black-tongue and pellagra), vitamin B₆ (rat dermatitis factor), and the "filtration factor" (chick dermatitis factor).

Effect of Various Meat Extracts on Pigment Production by *B. prodigiosus*. N. E. Goldsworthy and J. L. Still.—p. 631.

Pulmonary Schistosomiasis.—Pulmonary lesions due to emboli formed by ova are found in one-third of all necropsies on cases of schistosomiasis in Egypt; the ova of *S. haematobium* are those more commonly seen, but those of *S. mansoni* cause more severe lesions. The authors state that repeated embolization produces obliterative changes in the arterioles and the features of Ayerza's disease, with ultimate right heart failure; this condition was observed in 2 per cent. of all cases of schistosomiasis.

Virus in Chemically Induced Tumours.—When a fowl bears both a chemically induced and a Rous tumour the virus may be present in the former without modifying its nature or behaviour. This and related observations suggest that in the few instances when chemically induced tumours have been found transmissible by filtrates the presence of virus has been incidental. In the author's view "chemically induced tumours and virus tumours are essentially different in their nature and largely independent of and unaffected by each other."

Transmission of Rheumatic Fever.—Suspensions of virus-like bodies from exudates in cases of rheumatic fever, either alone or in combination with streptococci or streptococcus toxin, were injected into monkeys by various routes. No lesions characteristic of the human disease were produced.

Vaccination with B.C.G.—According to the authors the previous injection of B.C.G. increases the resistance of guinea-pigs to inoculation with a very small dose of virulent tubercle bacilli.

Transurethral Prostatic Resection.—Since the ordinary telescope with its small field does not tell one much about the amount of lateral resection, Alcock employs in addition a right-angled and a retrograde telescope. The former is valuable because of its large field and magnification; the latter, as giving a view of the adenoma such as one would get by suprapubic cystotomy. The verumontanum must be visualized throughout the operation; likewise care must be taken of the ureteric orifices. The retrograde view is especially valuable at the end of the operation in judging of the satisfactory abolition of the projection of the adenoma, or in identifying a remaining fragment as a thickening in the thin edge of the crater area of resection. The resection is judged at an end, not only when the bladder cavity and the top of the verumontanum are visible in one field, but also when, on rotating the retrograde telescope, it is possible to ascertain the perfect and equal thinness of the crest which should have replaced the intravesical prominence of the adenoma, and when the flanks of the crater are smooth and slope regularly towards the urethra, uninterrupted by the projection of any residual nodule.

Hormone Therapy in Prostatic Hypertrophy.—The general impression is that, in certain cases of prostatic enlargement, hormone therapy has been followed, after one or two months, by a diminution of symptoms, but only very rarely by a diminution of the size of the prostate. In the author's cases the symptom most benefited was pollakiuria in twenty-six out of thirty-five cases. Gross retention of urine was unaffected. Only in eight mild cases, with residual urine fluctuating between 50 and 200 c.cm., was there a diminution or disappearance of retention. The method is a palliative one, but not to be neglected.

Weekly Statistical Return of Infectious Diseases, United States, Foreign and Insular.—p. 1039

Epidemiology of Poliomyelitis.—In his review of outbreaks of poliomyelitis in the United States from 1916 to 1937 inclusive the author confesses that "little has been added to our knowledge in the past twenty years." The outbreaks occurred at intervals of three to five years, were widespread, and affected fairly large areas. Neither lines of traffic nor geographical obstacles (mountain ranges, large rivers) seemed to affect the spread. The severity of the disease and the intensity of incidence varied greatly even in adjacent districts, and these factors were apparently not related to density of population. The contribution presents factual material only, and no attempt is made to explain any of the facts presented.

Weekly Infectious Disease Reports: United States, Foreign and Insular.—p. 1106.

Metal-fume Fever.—Fumes from molten metals, commonly zinc and brass, produce a definite syndrome: dryness of throat, oppression of chest, cough, and rise of temperature followed by sweating. The onset occurs a few hours after leaving work; these symptoms passing off in twelve to twenty-four hours. A temporary immunity is established (for a few days), but cold and chilling of the body increase the liability to attack. There is no specific treatment, and prevention is limited to control of the fumes.

Weekly Infectious Disease Reports. United States, Foreign and Insular.—p. 1167.

Poliomyelitis.—This is a review of the epidemiology of the disease in the U.S.A. from 1915 onwards, the chief characteristic of which is its irregular behaviour. Protective measures are limited to ordinary hygienic precautions. No specific treatment is given, but early and careful handling of affected muscle groups is emphasized.

Washington vol. 53 July 15, 1938

- *Relative Amount of Ill-health in Rural and Urban Communities. H. F. Dorn.—p. 1181.
Prevalence of Undulant Fever (Brucellosis) in United States.—p. 1195.
*Studies on Fate of Selenium in the Organism. M. I. Smith, B. B. Westfall, and E. F. Stohman.—p. 1199.

Deaths during Week ended June 25, 1938: (a) In Group of Large Cities in United States; (b) Death Claims reported by Insurance Companies.—p. 1220.
Infectious Disease Returns: United States, Foreign and Insular.—p. 1221.

Relative Ill-health in Rural and Urban Communities.—A survey of fatal and non-fatal illness over a period of years in various-sized urban and rural communities shows that health in the former has improved to a greater extent than in the latter, but rural areas still have the advantage. Superior health services in urban areas account for diminished death rates from communicable and infantile diseases. The urban expectation of life in 1930 is still somewhat lower than the corresponding rural expectation in 1900. Mental illness shows the same trend as physical illness. If rural areas had the medical facilities of the urban, the differences would be still greater.

Selenium in the Organism.—Selenium, which may occur as a protein compound in oats and wheat correlated with sulphur, is retained to a considerable extent in the tissues—more so than artificially administered inorganic selenium—and may cause poisoning. Methods of detection and estimation are described. The paper is a continuation of a former contribution (*Public Health Reports*, 1937, vol. 52, p. 1171).

Cardiac Aneurysm. I. Parkinson, D. E. Bedford, and W. A. R. Thomson.—p. 455.
Genetics of Transposition of Viscera. E. A. Cockayne.—p. 479.

Heart Output in Congestive Failure.—The normal postural increase in heart output with slowing of the pulse which occurs following the change from an erect to a supine posture diminishes as heart failure progresses. The general heart output behaves similarly save at the stage when venous congestion appears; then there is a temporary increase. It is suggested that in cardiac failure the heart shows a diminished ability to respond to venous pressure increments, and that venous congestion is possibly a compensating mechanism.

Tuberculosis and Diabetes.—Pulmonary tuberculosis was present in 6.5 per cent. of new diabetics, but in only 0.7 per cent. of treated diabetics. Diagnosis of the early lesion is only possible by radiographs. In all cases the treatment of the

diabetes is of primary importance, and the prognosis is excellent if the lesion is discovered at an early stage.

Copper and Anaemia.—In six cases of iron-deficiency anaemia of infancy ferrous sulphate was given until the haemoglobin level showed no further rise; the addition of copper then produced a further increase. In three cases the iron was given in small doses so as to produce iron storage without increase of haemoglobin. Again administration of copper produced a rise. It is suggested that copper acts as a catalyst, enabling iron to be converted into such a form that it can be transported from the storage depots to the bone marrow and there turned into haemoglobin.

- Mortality from Cerebrospinal Fever in Hong Kong. K. H. Utley.—p. 287.
- Suicide by Ingestion of Derris Root in New Ireland. E. A. Holland.—p. 291.
- Some Vegetable Poisons of New Guinea. E. A. Holland.—p. 295.

Nutritional Macrocytic Anaemia.—According to the authors this is of two types—non-haemolytic, due to uncomplicated dietary deficiency, and haemolytic, where in addition there is increased phagocytosis of abnormal red cells by a reticulo-endothelial system hypertrophied as a result of some infection—for example, in Macedonian chronic malaria. Bone-marrow smears show: panmyelopathy characterized by erythropoiesis with megaloblastic degeneration; pathological precursors of the white cells; and abnormal megakaryocytes, which produce in the peripheral blood a megalocytic anaemia, leucopenia with a shift to the left, and thrombocytopenia. Purpura may be associated with thrombocytopenia, and is not due to vitamin C deficiency.

Bayer 205 Resistance in Trypanosomes.—The authors find that resistance of *T. gambiense* to Bayer 205 is an unstable character which decreases progressively on mechanical passage and disappears completely on cyclical transmission by *G. palpalis*.

Amoebic Invasion of Skin.—This is a description of a case of amoebic ulceration of the skin around a colostomy wound which rapidly responded to specific treatment.

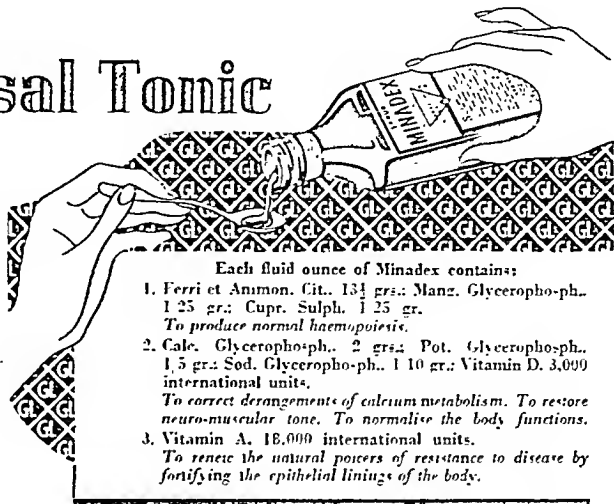

Bilharzial Asthma.—The author reports three cases of febrile asthma with urticaria, associated with schistosome infection. The asthma had no relation to local lung lesions of schistosomiasis, but was a specific allergic response to the infection.

**Enjoyable*

The Universal Tonic

Minadex owes not a little of its success to the fact that patients, especially children, thoroughly enjoy it and take it regularly. The three groups of therapeutic agents in Minadex are thus given full facilities to act. Minadex accelerates progress constructively; there are no temporary stimulants. The minerals, glycerophosphates and vitamins, by enriching the blood, strengthening the neuro-muscular system, and fortifying resistance to disease, build up positive health. Experience in hospitals and private practice proves abundantly that Minadex is a universal tonic, effective alike for convalescent children, 'run-down' adults, and for post-operative debility in the elderly.

In 6-oz. bottles, 2/6; 12-oz., 1/6; 80-oz. Winchester, reduced from 22/6 to 20/-. Prices (not applicable in *Libe*) are subject to usual professional discount.

FOOT COMFORT

By wearing 'APTERNA' HEEL-LESS SHOES

These shoes are designed in the common-sense knowledge that the majority of foot troubles are due in large measure to faulty footwear which aggravates the trouble and does not permit the natural exercise and freedom which is essential to foot health.

LANGHAM HOUSE, UPPER REGENT ST., W.1

Charles H. Baber

Any of the common foot ailments mentioned in the above diagram can be successfully prevented and relieved by prescribing the correct series of "Apterna" Heel-less Shoes.

"Apterna" Shoes are available for men and women and children.

Chas. H. Baber Ltd.

THROMBIN-COAGULANT-MAW DRESSINGS HAVE PROVED THEIR EFFICIENCY!

In the short time they have been on the market, Maw's T.C.M. Dressings have achieved remarkable success. Members of the profession who have used them have been impressed by the rapidity with which coagulation is achieved and numerous instances are recorded of severe haemorrhage being checked almost instantly. T.C.M. Dressings are treated with Thrombin-Coagulant-Maw, a preparation of natural Thrombin which accelerates blood coagulation and causes clotting within 5-15 seconds. They are supplied sterile, in sealed drums, ready for immediate use, and the series consists of special Lint Squares suitable for most purposes. Special T.C.M. Dressings can be supplied when required.

They cost only a trifle more than ordinary Dressings and are well worth the extra charge. We ask you to give them a fair trial, for we are confident that you will be satisfied with the results.

IMPORTANT ANNOUNCEMENT

'SUMMIT' Hypodermic Needle now ALL-BRITISH

The sole manufacturing rights of the 'SUMMIT' hypodermic needle having recently been taken over by S. and R. J. Everett and Company Limited, it is now entirely British.

EXCLUSIVE FEATURES OF 'SUMMIT':

(1) EASY TO WIRE.

Cleaning wire can be conveniently inserted through the mount due to a flared cone running down the needle bore.

(2) FIRM SILKY FIT.

Ensured by a soft durable metal seating to a specially reinforced mount (Pat. 7359).

(3) EASY TO ATTACH.

The shape of the 'Summit' mount enables it to be firmly gripped between the thumb and forefinger.

(4) LEGIBLE NUMBERING.

Owing to the shape and construction of the mount, the needle size is cast on it in very legible characters.

(5) APPEARANCE.

The special metal with which the mount is made retains a perfect appearance throughout the life of the needle.

The new Victor F-3 X-ray Unit

IS PORTABLE AND MOBILE

BUSY radiologists who require but do not wish to buy both an auxiliary X-ray unit for the consulting room AND a portable set, are choosing the new Victor F-3. For it is a low-priced combination unit quickly convertible for either purpose. Moreover, it covers a surprisingly wide range of practical service due to a 220% increase in radiographic power over the famous original Victor Model 1. Footcandle fine radiography and screening at strikingly low cost are further advantages you will appreciate.

STUDY THESE FEATURES

Portable and mobile * Wide range * Shockproof * Climate-proof * Easy to use * Operable from any plug point * Highly flexible and adaptable * Compact case only 21 x 14 x 8 inches * Weighs only 45 lbs. * Complete technique charts * Long-life, genuine Victor Coolidge tube * Accurate timer * Foot switch for screening * Convenient terms if desired *

For a demonstration without obligation, or the free descriptive booklet, simply fill up and post the convenient coupon.

WITHOUT OBLIGATION

WARM, DRY BEDS FOR OPERATION AND ACCIDENT CASES

In cases of sudden emergency and for everyday use, the "Thermega" Electrically-Heated Blanket is invaluable for providing warm, dry beds. Hospital and Nursing Homes throughout the country use "Thermega". It is the one proven remedy for driving out dampness and ensuring warmth at the turn of a switch.

The "Thermega" Electric Bed for local application is ideal for minor aches and for localising hot water bottles.

At all good stores, chemists, electricians; or from Thermega Limited, 51-53, Victoria Street, London, S.W.1.

ALUZYME NON-AUTOLYSED YEAST

Now extensively used by many Home and Overseas Services for Vitamin B deficiency conditions.

Yeast is a valuable therapeutic agent because it provides the whole of the Vitamin B Complex, and ensures total Vitamin B action. But if yeast is dried at high temperatures, or lysed with salt, or other chemicals, its therapeutic activity is greatly impaired. At times, Vitamin value is almost entirely lost.

Aluzyme is Brewers' Yeast dehydrated at such a low temperature that cell constitution is not affected; the nuclein and all factors of the B Complex remain fully active. This is shown by the B₁ Potency: 1140 INT. UNITS PER OZ., by live cell count, the glutathione reaction, and every applicable test.

In all forms of B avitaminosis the best results may be anticipated when Aluzyme is prescribed. It is specially recommended for neurotic affections, gastro-intestinal inflammation, toxæmias, and skin complaints, and in conjunction with iron in anaemia.

Samples, and full descriptive matter with tests, on request.

Darcuna Underwear for Luxurious Comfort . . .

Darcuna is luxury underwear and one of the most servicable fabrics made. In this rich quality wear a man feels well clad. It is soft and delightful to the touch but at the same time the wearing quality is extremely good. Darcuna is fully fashioned on the latest and best machines, ensuring perfectly shaped well-fitting garments. There is only one uniform high quality, but it is made in three weights for your choice, at 8/6, 9/6 and 10/6 per garment. From most hosiers and outfitters.

Made in Leicestershire,
famous for its hunting and
stockingers.

**Darcuna Underwear
by Two Steeples**

Two Steeples specialities also include No. 83 quality socks, 4/6 per pair. No. 72 socks, 3/6 per pair. St. Wolstan Wool Underwear from 12/6 per garment. Also quality knitted Hacking Sweaters, Waistcoats, Gilt Hose, etc.

Pattern booklet of Underwear and Socks sent on request to Dept 4 Two Steeples Ltd., Wiston, Leicestershire.

FORD'S

Gold Medal Absorbent
BLOTTING PAPER

Scientific Construction makes them highly efficient

Cozy Stoves burn open or closed on ordinary kitchen coal, and are guaranteed to burn 12 hours without attention. All doors are made to fit perfectly.

The amount of air required to ensure complete slow combustion depends upon the fuel used. The air regulating device in COZY STOVES is operated by a dial, and is most efficient.

Coal not burnt to ashes still gives off heat. Dropped through to the ash pan it is wasted. The new patent Rocking Grate in all large-size Cozy Stoves prevents that, and very little but the dead ashes fall through.

COZY STOVES are scientifically designed to give maximum heat with minimum fuel consumption during the whole 24 hours. For efficiency, adaptability, and economy, YOUR home needs a COZY. There's a wide range of models available to suit all requirements.

Write for Catalogue or see them at your local dealers.

COZY STOVES are available on easy terms.

THE EXAMINING BOARD IN ENGLAND

BY THE

ROYAL COLLEGE OF PHYSICIANS OF LONDON

AND THE

ROYAL COLLEGE OF SURGEONS OF ENGLAND

DIPLOMA IN ANAESTHETICS

(D.A., R.C.P. & S.Eng.)

The following clause in the regulations for the Diploma in Anaesthetics has now been withdrawn:—

"Until May 1st, 1938, it shall be open to the Royal Colleges, on the recommendation of the Committee of Management of the Examining Board, to grant the Diploma, without examination, to an Anaesthetist to a general hospital associated with a recognised medical school in the British Empire who has held this appointment for not less than ten years."

The Committee of Management has now been authorised by the Royal Colleges to consider applications up to, December 31st, 1938, for the award of the Diploma without examination from Anaesthetists who, while not strictly eligible under the previous

conditions, approach them so nearly as to give them, in the opinion of the Committee, the necessary experience and standing in the profession to justify their names being submitted to the Royal Colleges for the award of the Diploma.

Enquiries should be addressed to the Secretary of the Board, 8-11, Queen Square, London, W.C.1.

ROYAL EYE HOSPITAL

Medical School, St. George's Circus, S.E.1

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN (University of London.)

Applications are invited from medical graduates for the appointment of CURATOR of the ANATOMICAL MUSEUM, to give two half-days each week throughout the academic terms, beginning on appointment.

Applications should be sent by Wednesday, October 19th, to the undersigned, from whom further particulars can be obtained.

NANCIE MOLLER,

S. Hunter Street, Warden and Secretary.
Brixwick Square, W.C.1.

THE WARWICKSHIRE AND COVENTRY JOINT COMMITTEE FOR TUBERCULOSIS.

KING EDWARD VII MEMORIAL SANATORIUM,
Hertford Hill, near Warwick.

Applications are invited for the post of JUNIOR ASSISTANT MEDICAL OFFICER (man or woman) at the Memorial Sanatorium, near Warwick, of 225 beds.

The salary will be at the rate of £250 per annum, with board, lodging, and laundry in addition, and the successful candidate will be appointed for six months.

There are three other Medical Officers at the Sanatorium.

Applications, with copies of testimonials, should be forwarded direct to the Medical Superintendent at the Sanatorium, to reach him by not later than Thursday, October 20th, 1938.

Shire Hall, L. **EDGAR STEPHENS,**

Warwick. Clerk of the Joint Committee
October 3rd, 1938.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners with appropriate qualifications for two appointments as ASSISTANT PATHOLOGIST at Group Laboratories in the Council's pathological service. Salary £650-£25-£800.

Candidates should have special experience in one or more branches of pathology in relation to the diagnosis and treatment of disease.

Forms of application and further particulars (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 2), County Hall, Westminster Bridge, S.E.1., returnable by October 31st.

Canvassing disqualifies.

HULL CORPORATION HEALTH DEPARTMENT.

ASSISTANT MEDICAL OFFICER OF HEALTH (Female).

Applications are invited from duly qualified unmarried or widowed medical women, under the age of 40 years, and of not less than three years' standing in their profession, for the post of Assistant Medical Officer of Health.

Salary £600 per annum, rising, subject to satisfactory service, by annual increments of £25 to £700.

The duties consist mainly of work in the Maternity and Child Welfare Department, the School Medical Service, and the Tuberculosis Department.

Candidates must have had special experience in Paediatrics, and preference will be given to those possessing the Diploma in Public Health, or similar qualification, and to those with experience in a children's hospital.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on forms to be obtained from the undersigned, are returnable not later than 10 a.m. on Thursday, October 20th, 1938.

NICOLAS GEBBIE, M.D.,

Health Department, Medical Officer of Health,
Guildhall, Hull
October, 1938.

COUNTY BOROUGH OF BIRKENHEAD. DEPARTMENT OF THE MEDICAL OFFICER OF HEALTH.

BIRKENHEAD MUNICIPAL HOSPITAL. (560 Beds.)

SENIOR RESIDENT MEDICAL OFFICER.

Applications are invited for the above appointment at the Birkenhead Municipal Hospital.

Candidates must be male, unmarried, and duly qualified registered medical practitioners. As the duties are almost entirely of a medical nature preference will be given to candidates who have obtained higher qualifications in medicine and who have had previous medical experience at either a Voluntary or Municipal Hospital.

The appointed candidate will be a member of the staff of the Medical Officer of Health.

The remuneration attached to the appointment will be £350 per annum, rising by annual increments of £25 to a maximum of £450 per annum, together with board, residence, laundry, etc.

The appointment is subject to the Local Government and Other Officers' Superannuation Act, 1922, and is determinable by three calendar months' notice on either side.

Forms of application and further particulars relating to this appointment can be obtained from Dr. D. Morley Mathieson, Medical Officer of Health, 9, Hamilton Square, Birkenhead.

Canvassing, directly or indirectly, will disqualify the applicant.

Applications, endorsed "Senior Resident Medical Officer," should reach the undersigned not later than Saturday, October 22nd, 1938.

Town Hall, E. W. TAME,
Birkenhead Town Clerk.

CITY OF PLYMOUTH. CITY GENERAL HOSPITAL. (570 Beds.)

Applications are invited from duly qualified and registered Medical Practitioners for the post of JUNIOR ASSISTANT MEDICAL OFFICER.

Salary at the rate of £250 per annum, with full residential emoluments. All fees received by the Officer must be refunded to the Council.

The appointment will be for a period of six months in the first instance, and renewable for a further period of six months, and will be terminable by one month's notice on either side.

The duties of the post will be largely on the surgical side of the Hospital.

Further details may be obtained from the Medical Superintendent.

Forms of application may be obtained from the undersigned and should be forwarded, together with copies of not more than three recent testimonials, not later than October 24th, 1938.

Town Hall, Medical Officer of Health,
Stonehouse, Plymouth.

LONDON COUNTY COUNCIL. INFECTIOUS HOSPITALS.

Applications invited from Medical Practitioners of at least one year's standing for appointment as assistant medical officers, grade II, at various hospitals for infectious diseases. Salary £250 a year, together with board, lodging, and washing. Experience in a resident appointment in a general hospital for at least six months desirable. Appointments are for one year only in the first instance (renewable for a second year under conditions).

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division, 2A), County Hall, S.E.1, returnable by October 21st. Canvassing disqualifies.

MIDDLESEX COUNTY COUNCIL.

PUBLIC HEALTH DEPARTMENT, 10, Great George Street, Westminster, S.W.1.

Additional ASSISTANT MEDICAL OFFICER OF HEALTH required. Must be medical practitioner with degree or diploma in Sanitary Science, Public Health, or State Medicine; previous hospital appointments, good knowledge of clinical medicine and public health organization, and practical experience in public health administration essential.

Pensionable staff, subject to medical examination. Salary £800-£50-£1,000 p.a., and reasonable out-of-pocket travelling expenses.

Duties on central staff under supervision and control of County Medical Officer. Whole-time duties—no other appointments or private practice permitted.

DENTAL ANAESTHETISTS required for duties as and when required at school dental clinics in Friern Barnet, Wembley, South Harrow, Hayes, Southall, Uxbridge, and Staines. Must be registered medical practitioners with special knowledge and experience in administration of dental anaesthetics.

Fee £1 11s. 6d. for 1½-hour session approximately weekly and arranged as far as possible to suit anaesthetists' convenience.

Apply for either post to the undersigned by October 29th, 1938, giving age, qualifications, and special experience, and copies of not more than three recent testimonials. Endorse envelopes either "Asst. C.M.O." or "Dental Anaes."

Canvassing, directly or indirectly, disqualifies.

C. W. RADCLIFFE, "Z."

Guildhall, Clerk of the County Council,
Westminster, S.W.1.

SURREY COUNTY COUNCIL.

PUBLIC HEALTH DEPARTMENT.

EPSOM COUNTY HOSPITAL (330 Beds).

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of Resident Assistant Medical Officer at the Epsom County Hospital. Applicants should preferably have had previous resident hospital experience and have had postgraduate experience in maternity work, minor surgery, and anaesthetics.

The appointment is for a period of six months, renewable for a further period of six months, and the salary is at the rate of £250 per annum, together with full residential emoluments valued at £125 per annum.

Applications, stating age, qualifications, and experience, and enclosing copies of not more than three recent testimonials, should be addressed to the Medical Superintendent, Epsom County Hospital, Dorking Road, Epsom, so as to be received not later than October 19th, 1938.

County Hall, DUDLEY AUKLAND,
Kingston-upon-Thames, Clerk of the Council.
October 10th, 1938.

LANCASHIRE COUNTY COUNCIL.

WHISTON COUNTY HOSPITAL, near Prescot.

APPOINTMENT OF RESIDENT MEDICAL OFFICER.

Applications are invited for the appointment of Resident Medical Officer (unmarried) at the Whiston County Hospital, near Prescot (500 beds).

Applicants must have held previous hospital appointments in which they have gained experience in clinical medicine and pathology, and they should hold one of the higher medical qualifications.

The salary is at the rate of £400 per annum, together with the usual residential emoluments. The appointment is for a period of one year in the first instance, but may be renewed for a further period of one year.

Forms of application may be obtained from the County Medical Officer of Health, Hospital and Medical Department, County Offices, Preston, to whom all applications must be returned not later than October 31st, 1938.

County Offices, GEORGE ETHERTON,
Preston, Clerk of the County Council.
October 10th, 1938.

LONDON COUNTY COUNCIL.

Applications invited from Medical Practitioners of at least one year's standing to undermentioned positions. Candidates must have held resident appointment in a general hospital for at least six months. Married quarters not available.

ASSISTANT MEDICAL OFFICERS (grade I).—Salary £350-£25-£425, with board, lodging, and washing.

(a) PADDINGTON HOSPITAL, Harrow Road, W.9

(b) HACKNEY HOSPITAL, Homerton High Street E.9.

Obstetrical and gynaecological experience essential (both positions).

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division, 2A), County Hall, S.E.1, returnable by October 28th. Canvassing disqualifies.

COUNTY BOROUGH OF HASTINGS

PUBLIC HEALTH DEPARTMENT.

DEPUTY MEDICAL OFFICER OF HEALTH. DEPUTY SCHOOL MEDICAL OFFICER, etc.

The Council invite applications for the appointment of Deputy Medical Officer of Health and Deputy School Medical Officer (male or female) at a salary of £650 per annum, rising by annual increments of £25 to £700 per annum, with an allowance of £85 per annum for use of motor car and other local travelling expenses.

Applicants must be medical men or women, under 40 years of age, holding a special qualification in State Medicine or a Diploma in Public Health, with not less than three years' experience after qualifying.

Preference will be given to applicants who have had experience of Public Health Administration and school medical work, including refractive, infectious diseases, and other branches of public health work, and have held a resident hospital appointment.

The person appointed will work under the direction and control of the Medical Officer of Health, acting as his deputy, and, while mainly employed in the School Medical Service or in Maternity and Child Welfare Work, will be required to assist in any Department of the Health and/or Medical Services of the Corporation.

The person appointed will be required to reside within the Borough of Hastings, to devote the whole of his or her time to the duties of the office, to contribute to the Council's Superannuation Scheme, and to pass a medical examination.

Canvassing will be a disqualification.

Applications, on forms to be obtained from the undersigned, must be addressed to me endorsed "Deputy Medical Officer" and delivered at the Town Hall, Hastings, not later than Saturday, October 22, 1938.

D. W. JACKSON,
Town Clerk.

COUNTY BOROUGH OF WEST HAM

EDUCATION DEPARTMENT.

Applications are invited from fully qualified Dentists (male) for appointment as SENIOR SCHOOL DENTAL OFFICER. The person appointed will be responsible to the School Medical Officer, and will be required to devote the whole of his time to the service of the Education Committee, to co-ordinate and supervise the work of the existing dental staff, and also to undertake clinical work. Salary £550 per annum, rising by annual increments of £25 to a maximum of £675 per annum, all fees received from whatever source to be paid over to the Council.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Acts and to medical examinations as required by the Council for the purposes of the Acts, and the statutory contributions will be deducted from the salary.

Canvassing members of the Education Committee or the Council, either directly or indirectly, will be considered a disqualification.

Forms of application, together with particulars of duties, may be obtained from the School Medical Officer, Municipal Health Offices, 83, Strand Road, E.15, upon receipt of a stamped addressed envelope, and should be returned to the undersigned not later than Saturday, October 22nd, 1938.

CHARLES E. CRANFIELD,
Town Clerk and Education Officer.
Education Offices,
95, The Grove, Stratford, E.15.
October 1st, 1938.

COUNTY BOROUGH OF DEWSBURY

DEPUTY MEDICAL OFFICER OF HEALTH and DEPUTY SCHOOL MEDICAL OFFICER

Applications are invited from duly qualified and registered medical practitioners for the post of Deputy Medical Officer of Health and Deputy School Medical Officer.

Applicants should have had at least three years' experience since qualification and possess a D.P.H. The duties include general Public Health, School Medical work (including refractive, Child Welfare, and Tuberculosis).

The salary is £600 per annum, rising by annual increments of £25 to a maximum of £675 per annum. A motor-car allowance of £50 per annum. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Particulars of the duties and terms and conditions of the appointment, together with application forms, may be obtained from Dr. J. F. Galloway, Medical Officer of Health, Public Health Department, Municipal Buildings, Halifax Road, Dewsbury, to whom applications, accompanied by copies of not more than three recent testimonials, should be delivered not later than Monday, October 17, 1938.

Canvassing in any form will be a disqualification.
Town Hall, HOLLAND BOOTH,
Dewsbury, Town Clerk.
October 10th, 1938.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than November 21st, 1938.

ROYAL NAVAL DENTAL SERVICE

Applications are invited for appointment to commissions as DENTAL OFFICERS in the ROYAL NAVY.

Candidates, who must be British subjects below the age of 28 years, must hold the degree or diploma of a British University or College of Surgeons, and be registered under the Dentists Acts or Medical Acts. Unmarried candidates are preferred. No examination in professional subjects will be held, but candidates will be required to attend at the Admiralty for interview, and for physical examination as to their fitness for service in any part of the world.

Successful candidates will be appointed to short service commissions as Surgeon Lieutenants (D) and will receive a grant of £50 towards the cost of providing the necessary uniform on entry. Vacancies in the permanent list will be filled by selection from among officers holding short service commissions who desire to make the Royal Naval Dental Service their permanent career. Officers not transferred to the Permanent List will, on the termination of their short service commission after six years' service, be eligible for a gratuity of £1,000.

Opportunities are available for officers on the permanent list for post-graduate study. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances. Naval Dental Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers.

Application Forms and copies of the regulations for entry and conditions of service, rates of pay and allowances, etc., may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of Dental Schools.

CITY OF BIRMINGHAM.

Maternity and Child Welfare Department.

Canwell Hall Babies' Hospital. (84 Beds.)

A WOMAN RESIDENT MEDICAL OFFICER is required for a period of six months. Duties to commence on December 6th.

Applicants should have had previous experience as a resident house physician, preferably in a Children's Hospital.

Salary £250 per annum, with board and laundry. Applications, endorsed "Resident Medical Officer," and accompanied by copies of three recent testimonials, to be made on a form obtainable from the Medical Officer of Health, Council House, Birmingham, 3, and returned to him on or before October 26th.

SOUTHERN RHODESIA MEDICAL SERVICE GOVERNMENT MEDICAL OFFICER.

Applications are invited from fully qualified, unmarried, male Medical Practitioners with surgical experience for appointment as a Government Medical Officer in the Southern Rhodesia Medical Service.

Salary will be on the scale £600-£25-£750 per annum. There is also a senior grade (£750-£25-£900) to which promotions are made as vacancies occur. Salary will commence from the date of assumption of duty in Southern Rhodesia. In addition, private practice is allowed.

The successful applicant will be required to sign an agreement for three years' service. In the first instance, and thereafter may make application to be placed on the pensionable establishment.

A free second-class steamship passage to Cape Town and first-class railway ticket thence to Southern Rhodesia will be provided.

Candidates, either directly or indirectly, will disqualify applicants.

The applicants should state the date on which they would be prepared to leave England if appointed.

Applications, stating age, qualifications, and experience, together with copies of testimonials, should reach the Official Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429, Strand, London, W.C.2 (from whom further particulars and application form may be obtained), not later than October 24th, 1938.

COUNTY BOROUGH OF EASTBOURNE.

ST. MARY'S MUNICIPAL HOSPITAL.
RESIDENT HOUSE SURGEON.

Applications are invited from unmarried registered Medical Practitioners for appointment as Resident House Surgeon at the above Hospital.

Salary £150 per annum, with board, residence, etc. The appointment is for twelve months, determinable at any time by one month's notice.

Application forms, together with conditions of appointment and duties, can be obtained from the undersigned. The application form, when completed, should be returned to me not later than October 28th, 1938.

W. G. VILLOUGHBY,
Medical Officer of Health.
The Avenue, Eastbourne.

BUCKINGHAMSHIRE COUNTY COUNCIL. ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from registered Medical Practitioners, not over 40 years of age, holding a reasonable qualification in Public Health, Sanitary Science, or State Medicine, to act as Assistant County Medical Officer of Health and Assistant School Medical Officer of Health.

The duties will pertain mainly to School Medical Inspection and Maternity and Child Welfare work, but there will be opportunities for the investigation of sanitary conditions generally.

The salary is £500 per annum, rising, subject to satisfactory service by annual increments of £25 to a maximum of £700 per annum.

The successful applicant will be required to pay contributions under the Local Government and Other Officers' Superannuation Act, 1922, and to pass a medical examination as to physical fitness, the final appointment being subject thereto.

Particulars and conditions of the appointments are set out on the form of application, which can be obtained from the undersigned.

Applications, on the prescribed form, accompanied by copies of not more than three recent testimonials, which will not be returned, should be addressed to the Clerk of the Bucks County Council and delivered at the County Hall, Aylesbury, not later than 3.15 p.m. on Friday, October 28th, 1938, marked "Assistant Medical Officer."

County Hall, Aylesbury. GUY R. CROUCH,
Clerk of the Bucks County Council.

SWANSEA COUNTY BOROUGH. RESIDENT MEDICAL OFFICER.

HILL HOUSE INFECTIOUS DISEASES HOSPITAL.

The Council invite applications for the above appointment from duly qualified unmarried (male) Medical Practitioners. The salary will be at the rate of £350 per annum, together with emoluments. Previous experience in an Infectious Disease Hospital is desirable. The appointment is for one year.

Applications (on special forms with particulars of duties) can be obtained from the Medical Officer of Health, Public Health Office, Swansea, to be sent in not later than Wednesday, October 19th, 1938.

ESSEX COUNTY COUNCIL.

JUNIOR ASSISTANT MEDICAL OFFICER.

The County Council of the Administrative County of Essex invite applications for the appointment of Junior Assistant Medical Officer at the Black Notley Sanatorium, near Braintree.

This sanatorium contains 300 beds for the treatment of pulmonary and non-pulmonary tuberculosis in men, women, and children, and possesses all modern facilities for diagnosis and treatment, and a staff of visiting specialists.

The appointment is limited to a period of one year, and the salary will be at the rate of £250 per annum, together with board, lodging, and laundry. The successful applicant will be required to pass a medical examination, and will be subject to the Council's Sick Pay Rules and Regulations, a copy of which will be forwarded on application.

Preference will be given to candidates who have held an appointment as House Surgeon with orthopaedic experience.

Applications, in candidate's own handwriting, stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials (which will not be returned), should be addressed to me and delivered at the County Hall, Chelmsford, not later than 10 a.m. on Thursday, October 27th, 1938.

County Hall, Chelmsford, E. S. HOLCROFT,
Clerk of the County Council.
October 10th, 1938.

COUNTY BOROUGH OF DERBY.

DERBY CITY HOSPITAL.

ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited for the post of Assistant Resident Medical Officer (male) at the above Hospital of 300 beds. This Hospital provides treatment for acute medical and surgical cases, obstetrics, and children's diseases, etc.

Candidates must be registered in medicine and surgery.

The appointment is for a period of six months; two months' notice of termination of duties may be given on either side. The successful applicant will be required to commence duties as soon as possible.

Salary at the rate of £200 per annum, with board and residence.

Applications, stating age, experience, and accompanied by three recent testimonials, should be sent to the undersigned as soon as possible.

GORDON LILICO,
Medical Officer of Health.

Public Health Department,
1, Derwent Street, Derby.

CITY OF MANCHESTER.

WITHINGTON HOSPITAL. (1,184 Beds.) (Recognized under the Regulations for the F.R.C.S.)

The Public Health Committee invites applications from registered Medical Practitioners for the post of assistant to the RESIDENT OBSTETRICAL OFFICER—Grade II—at the above-named hospital. The salary for the appointment is £250 per annum, with board, residence, and laundry in addition, subject to the Manchester Corporation conditions of service.

The appointment will be made in the first instance for a period of six months, renewable for a further six months, but not renewable thereafter.

Full information and forms of application may be obtained from the Medical Officer of Health, Town Hall, Manchester, 2, and applications for the post must be received by him not later than Monday, October 24th, 1938.

Town Hall, Manchester, 2, R. H. ADCOCK,
October 11th, 1938. Town Clerk.

ROYAL SURREY COUNTY HOSPITAL,

Guildford.

WANTED, NOVEMBER 1st. HOUSE PHYSICIAN AND CASUALTY OFFICER (Male).

Six months' appointment—recognized for M.D. examination. Salary £150 per annum, with board, residence, and laundry.

Applications, stating age and essential particulars, with copies of not more than three testimonials, to reach the Secretary-Superintendent not later than first post on Wednesday, October 26th.

ROYAL SUSSEX COUNTY HOSPITAL,

Brighton (272 Beds.)

CASUALTY HOUSE SURGEON (male) required as soon as possible. Salary £120 p.a., with board, residence and laundry. Candidates must hold medical and surgical qualifications of the British Empire and be duly registered under the Medical Act. They must be unmarried and when elected under 30 years of age.

Applications, with copies of recent testimonials, to be forwarded to the undersigned.

L. L. W. LANCASTER-GAYE,
Secretary-Superintendent.

MUNICIPALITY OF SINGAPORE.

Straits Settlements.

APPOINTMENT OF ASSISTANT HEALTH OFFICERS.

The Municipal Commissioners of Singapore require two Assistant Health Officers (male) for their permanent staff, the appointments being in the first instance on a three-years' agreement. The services of one will be required on January 1st, 1939, and the second early in March, 1939.

Candidates must be British subjects and must hold the qualifications in Medicine and Surgery of a recognized British Medical School, and registrable in the Straits Settlements.

The appointments will be in Class III of the Municipal Salary Scheme for Senior Officers, viz.: \$4,800 p.a. rising by annual increments of \$300 to \$7,200 p.a., and thereafter by annual increments of \$480 to \$9,600 p.a. The minimum salary for a candidate in possession of the Diploma in Public Health will be \$6,000 p.a. and a higher commencing salary up to, but not exceeding \$7,200 p.a. may be paid to a candidate according to experience.

In no case will any successful candidate be eligible for promotion above Class III in the department unless he is in possession of a registrable Diploma in Public Health.

Free 2nd Class passage will be granted with half salary during the voyage out.

An allowance for duty transport will be granted.

The selected candidates must pass a medical examination as to their fitness for service in the tropics, and will be required to join the Provident Fund.

A knowledge of mosquitoes and anti-mosquito work is desirable.

Applications, stating whether married or single, giving age and place of birth, with details of education, training and experience generally, accompanied by copies (not originals) of not more than three recent testimonials, to be lodged with Messrs. PERCE AND WILLIAMS, Chartered Civil Engineers, 1, Victoria Street, Westminster, S.W.1, Agents to the Commissioners, not later than October 31st, 1938.

Further particulars, if required, can be obtained from the Agents.

METROPOLITAN BOROUGH OF HAMMERSMITH.

DEPUTY MEDICAL OFFICER OF HEALTH AND TUBERCULOSIS OFFICER.

Applications are invited from gentlemen not exceeding 40 years of age for the appointment of Deputy Medical Officer of Health and Tuberculosis Officer for the Borough of Hammersmith.

The salary attaching to the appointment is £750 per annum, rising by annual increments of £50 to a maximum of £1,000.

Candidates must possess the Diploma of Public Health as well as the qualifications prescribed by the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930, with experience in a sanatorium or other tuberculosis institution, or otherwise in whole-time work in relation to tuberculosis. They should be experienced in artificial pneumothorax treatment.

The gentleman appointed will be required to devote his whole time to the duties of the office. He will be required to assist in the general work of the Public Health Department and to perform the duties of the Tuberculosis Officer under the direction and supervision of the Medical Officer of Health. He must be prepared to attend the meetings of the Council and such Committees as are directly concerned with the work of the Public Health Department.

The appointment will be subject to the provisions of the Council's Superannuation Scheme, and the successful applicant will be required to pass a medical examination.

Applications, on forms to be obtained from the undersigned, accompanied by copies of not more than three recent testimonials, must be delivered at the Town Hall, Hammersmith, W.6, in envelopes endorsed "Deputy Medical Officer of Health," not later than October 31st, 1938.

Canvassing will be a disqualification.
Town Hall, Hammersmith, W.6, HUGH ROYLE,
October, 1938. Town Clerk.

WILSON HOSPITAL, MITCHAM, SURREY.

(72 Beds.)

RESIDENT MEDICAL OFFICER, male or female, required from November 24th next. Salary £150 per annum, with board, residence, and laundry.

The appointment is for six months, renewable for a further six months at the discretion of the Committee.

The Hospital is quite modern and exceptionally well equipped, and carries out work of a character which gives the Resident Medical Officer a considerable amount of experience.

Applications, with copies of three testimonials, stating age, qualifications, and experience (particularly anaesthetics), should be sent at once to the Hon. Secretary, "Greenview," Lower Green, Mitcham.

STAFFORDSHIRE COUNTY COUNCIL.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from medical men holding the Diploma of Public Health for the above post. Candidates should have had at least three years' experience in the practice of their profession subsequent to qualification. Preference will be given to those who have held residential hospital appointments.

The person appointed will work under the direction of the County Medical Officer and the duties of the office will include school medical and maternity and child welfare work, in addition to such general public health work as may from time to time be prescribed.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £700 per annum, subject to a deduction of 5 per cent, established under the Local Government and Other Officers' Superannuation Act, 1922.

The successful candidate will be required to undergo a medical examination and to produce a birth certificate.

The appointment will be subject to three calendar months' notice on either side.

Forms of application may be obtained from the undersigned and should be returned by first post on October 27th, 1938, together with copies of not more than three testimonials.

Candidates must state in their applications whether or not they are in any way related to a member of the County Council.

Canvassing, either directly or indirectly will be a disqualification.

Candidates receiving no reply by November 12th, 1938, may assume the vacancy to be filled.

H. L. UNDERWOOD,

Clerk of the County Council.
County Buildings,
Stafford.
October 10th, 1938.

THE CHILDREN'S HOSPITAL,

King Edward VII Memorial, Birmingham, 16.

Selected panel of 60. Average fees about 7/-, Good house with ample accommodation. Rent £170 p.a., or smaller house or suitable flat available if preferred. Premium £2,000.
4. SURREY.—PARTNERSHIP.—ONE-HALF SHARE is offered in old-established good mixed-class Practice situated in very favourite residential locality and averaging for past 3 years £2,627 p.a. Panel of about 2,000. Very pleasant house with nice garden, rented at £109 p.a. Premium 2 years' purchase. Vacancy occurs through illness of senior partner. Incoming partner must be experienced, preferably married, and accustomed to better-class work.
5. HANTS.—PARTNERSHIP.—ONE-HALF SHARE in well-established middle-class Practice producing approximately £2,500 p.a. Panel of 1,350 and appointments worth £273. Fees 3/6 to 21/-, Choice of houses. Premium 2 years' purchase. Incoming partner must be experienced and preferably aged between 35-45.
6. SURREY.—DEVELOPING DISTRICT.—Increasing PRACTICE producing about £850 p.a., including panel of 450. Semi-detached freehold house with 2 bedrooms, etc. Freehold for sale, or smaller house available. Premium 1 year's purchase.
7. WITHIN 15 MILES NORTH OF LONDON.—DEVELOPING AREA.—NUCLEUS of Practice at present producing about £300 p.a., with good scope. Very nice house with ample accommodation can be rented or purchased. Premium 1 year's purchase.
8. LONDON.—BETTER-CLASS NON-PANEL NON-DISPENSING PRACTICE producing between £1,100 and £1,200 p.a., 21/- fees. Large house with ample accommodation. Leasehold for sale, or other premises can be taken. Premium £1,750.
9. LONDON, W.—PARTNERSHIP.—A SHARE producing about £2,200 p.a., in very high-class Practice. Good house with ample accommodation. Leasehold for sale.
10. S. WALES.—Old-established mainly contract PRACTICE producing last year £2,200, of which £2,050 is from contract and panel. Suitable house available. Future prospects considered excellent, as new works recently erected in district. Premium £3,500, part by instalments.
11. NORTH LONDON.—Very sound upper- and middle-class PRACTICE averaging about £2,500 p.a. Panel of about 1,000. Excellent house, specially built, with ample accom. Freehold for sale. Premium 2 years' purchase.
12. WARWICKSHIRE.—PROSPEROUS TOWN.—ONE-HALF SHARE of good mixed-class Practice at present averaging about £1,500 p.a., with exceptional scope. Panel of 1,100 (steadily increasing). Choice of houses. Premium 2 years' purchase.
13. OUTLYING NORTHERN SUBURB.—Very sound PRACTICE in developing area, producing over £2,000 p.a. including panel of about 1,500. Very nice house and garden. Premium 2 years' purchase.
14. MIDDLESEX.—OUTLYING DISTRICT.—NUCLEUS of PRACTICE producing about £300 p.a. with scope. Very good house with ample accom. and large garden. Freehold for sale. Premium 1 year's purchase.
15. SOUTH COAST RESIDENTIAL TOWN.—Upper- and middle-class non-dispersing PRACTICE producing for last 12 months £1,622, including panel of about 900 and appointments worth about £100 p.a. Well situated house near sea with 3 reception, 4-5 bedrooms, large garden, garage. Leasehold for sale. Premium £3,500.
16. HOME COUNTIES.—PARTNERSHIP.—ONE-FIFTH SHARE (after preliminary assistantship) is offered in exceptionally good old-established practice averaging £4,800 p.a. Panel about 2,700. Fees 3/6 to 21/-. Choice of houses. Incoming partner must be experienced, accustomed to better-class work. Prospect of hospital appointment. Premium 2 years' purchase.
17. DEVELOPING NORTHERN SUBURB.—Rapidly increasing mixed-class PRACTICE on new estate with excellent scope. Gross cash receipts for last 12 months about £1,200. Lowest fee 3/6. Choice of houses. Premium 2 years' purchase.
18. ESSEX.—COUNTRY DISTRICT WITHIN 45 MILES OF LONDON.—Old-established practically unimproved good mixed-class PRACTICE producing last year £3,000 with substantial panel. Very nice house with ample accommodation and all modern convenience. Freehold for sale. Premium £5,500. Ample scope for expansion.
19. LANCs.—N.W. COAST.—SURGICAL OPENING.—PARTNERSHIP.—ONE-THIRD SHARE (after preliminary assistantship) is offered in old-established practice producing £4,500 p.a. Panel of 1,600. Suitable house available. Premium 2 years' purchase. Incoming partner should be experienced and preferably have the fellowshipship.
20. LONDON, S.E.—Old-established PRACTICE at present producing £600 p.a. Panel of 1,000. Leasehold house with ample accommodation. Price £1,300. Premium £1,000.
21. LONDON.—OUTLYING WESTERN DISTRICT.—Old-established PRACTICE with good scope. Present income £560 including panel of 890 and appts. worth £40 p.a. House on rental at £100 p.a. Moderate premium.
22. NORTH OF ENGLAND.—LARGE TOWN.—Well-established chiefly working-class PRACTICE producing £2,250 p.a. Panel of 2,300. P.M.S. £450-£500 p.a. Appointments £100 p.a. Suitable house (2 reception, 4 bedrooms, etc., garden, garage) Price £1,800, part on mortgage. Premium 2 years' purchase.
23. AST TOWN.—Better-class non-panel and offering good scope. Detached bay, with ample accommodation. Sport of all kinds and good educ. facilities. Premium £1,400 for quick sale.
24. SOUTH OF ENGLAND.—FAVOURITE RESIDENTIAL TOWN WITHIN 10 MILES OF THE COAST.—PARTNERSHIP.—HALF-SHARE in old-established good-class practice producing over £3,200 p.a. Panel of about 1,500. Appointments worth about £600 p.a. Very nice house in good repair, with 2 reception, 4 bedrooms, etc. First-rate schools and good social and sporting facilities. Premium 2 years' purchase. Incoming partner must be experienced, aged about 35-40, and preferably have a knowledge of anaesthetics.
25. MIDLANDS.—COUNTY TOWN.—PARTNERSHIP.—ONE-THIRD OR ONE-HALF SHARE in old-established mixed-class Practice having exceptional scope for increase. Gross cash receipts for past 12 months approximately £2,000 p.a., including panel of £1,100 p.a. and P.M.S. £450 p.a. Fees from 3/6. Suitable house with ample accommodation, garden, garage, electric light. Rent about £70 p.a. Premium 2 years' purchase. Incoming partner must be experienced, preferably Scottish or English, and married.
26. LONDON, S.E.—PARTNERSHIP.—ONE-HALF SHARE in well-established good mixed Practice, producing approximately £2,600 p.a., including panel of about 1,900. Fees from 1/6. Suitable house available with 3 bedrooms, etc. Premium 2 years' purchase. Incoming partner must be experienced and energetic worker.
27. LONDON, S.W.—CENTRAL DISTRICT.—Recently established better-class non-dispersing PRACTICE with scope for OPHTHALMOLOGY producing nearly £1,200 p.a., of which about £200 is derived from refractions. Fees 10/6 to 21/-. House contains 2 reception, 6 bedrooms and Professional rooms. Price, leasehold £950 p.a. Premium £1,500, part by arrangement.
28. MANCHESTER.—Very old-established middle- and working-class PRACTICE averaging for last 3 years £1,380 p.a. Panel of 840. Appointments about £180 p.a. Fees from 3/6. House with 3 bedrooms, etc., garden, garage, electric light. Price freehold £950. Premium for quick sale, 11 years' purchase, part by instalments.
29. LONDON, EAST.—Old-established mixed-class PRACTICE averaging about £2,700 p.a., including panel of about 1,300, and increasing. Separate surgery premises. Premium 2 years' purchase.
30. LONDON, N.W.—GROWING RESIDENTIAL DISTRICT.—PARTNERSHIP.—Guaranteed share in rapidly expanding Practice producing to commence about £500 p.a., with increase later. Suitable detached house on rental at £52 p.a. Incoming partner must be experienced and energetic.
31. KENT.—RAPIDLY EXPANDING DISTRICT.—Well-established middle- and working-class PRACTICE producing about £1,700 p.a., including panel of nearly 1,400. Good house with 2 reception, 5 bedrooms, etc., large garden. Inclusive rent £130 p.a. Premium 2 years' purchase.
32. MIDDLESEX.—DEVELOPING AREA.—Well-established mixed-class PRACTICE averaging over £1,000 p.a., including panel of 850 and appointments worth about £100 p.a. Corner house with 2 reception, 4 bedrooms, etc., garden, garage. Rent £100 p.a. Premium £2,000 or near offer for quick sale.
33. KENT COAST.—PARTNERSHIP.—ONE-THIRD OR ONE-HALF SHARE in middle-class Practice averaging £1,650 p.a. Panel of about 2,000. Excellent modern house available by purchase or rental. Premium 2 years' purchase. Incoming partner must be experienced and well qualified.
34. YORKS.—COUNTRY PRACTICE.—Old-established, income about £1,030 p.a., with scope for increase. About £350 of present income is derived from panel of some 500 patients. Good freehold house with ample accommodation, garden and garage. Price for practice and house £3,600 of which about £1,900 may be left on mortgage.
35. GLDS.—NEAR WYE VALLEY.—Very sound PRACTICE producing about £1,300 p.a., including panel of 1,150 patients and appointments worth about £60 p.a. Low expenses. Detached house with large garden, 5 bedrooms, etc. Freehold. Premium £2,200 purchase.
36. FAVOURITE SOUTH COAST RESORT.—Private and better-class PRACTICE averaging over £1,000 p.a. Minimum fee 5/-. No dispensing. Scope for panel if desired. Modernized house with ample accommodation. Premium £1,000.
37. ESSEX.—PARTNERSHIP after ASSISTANTSHIP of 3 months in chiefly better-class Practice offering considerable scope. Good house available on rental. Share worth £800/£900 p.a. at 2 years' purchase.
38. WEST LONDON RESIDENTIAL DISTRICT.—Old-established chiefly upper- and middle-class PRACTICE averaging approximately £1,500 p.a. Selected panel of 114 patients, but scope for increase if wished. Fees 5/- to 21/-. Non-dispersing. Scope for increase as large blocks of modern flats in course of erection. Excellent house with ample accom. Premium £3,000.
39. MIDLANDS.—GOOD RESIDENTIAL COUNTRY DISTRICT.—Compulsory PRACTICE at present producing about £750 p.a., but capable of considerable expansion. Choice of 2 houses. Moderate premium for quick sale. Vendor retiring through ill-health.
40. DURHAM COUNTY.—Old-established industrial PRACTICE producing £2,000 p.a., of which only about £450 is derived from private work. Panel of over 2,100 units. Practice has been held by the vendor for about 20 years. Premium £4,000 to include book debts, drugs, surgery furniture, etc. (part by arrangement), or £3,600 cash down.

ASSISTANTS REQUIRED.—Several good vacancies. Full details on application.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

Valentine's Meat-Juice

In Typhoid Fever, Diarrhoea and Cholera Infantum, when it is Essential to Sustain the patient without irritating the Digestive Organs, the Ease of Assimilation and Power of Valentine's Meat-Juice to Restore and Strengthen has been demonstrated in Hospital and Private Practice.

When Other Food Fails

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

YES

YOU CAN SAFELY PRESCRIBE THIS TEA FOR ALL YOUR PATIENTS

Not because it is specially prepared in any way whatever, but simply because it is harmless to the most delicate digestion. The Doctor's China Tea is a blend of the choicest teas that China grows—teas which contain comparatively so little tannin that they can be enjoyed by all. For over a quarter of a century The Doctor's China Tea has been recommended by the medical profession—even in cases of dyspepsia and gastritis. A generous free sample will be sent to any doctor who would like an opportunity of trying the tea.

THE

DOCTOR'S CHINA TEA

Priced at 3/6, 3/6, 4/2, and a
super quality at 4/8 per lb.

BIOCHEMISTRY FOR MEDICAL STUDENTS

By W. V. THORPE, M.A., Ph.D.
Reader in Chemical Physiology, University
of Birmingham.

4 Plates and 33 Text-figures. 12s. 6d.

This volume is an endeavour to supply the student of medicine or dentistry with those Biochemical facts that he will require especially.

*To help
the Doctor*

THREE NEW BOOKS

ELEMENTARY ANATOMY AND PHYSIOLOGY

By JAMES WHILLIS, M.D., M.S.,
F.R.C.S.

University Reader in Anatomy, Guy's
Hospital Medical School.

87 Illustrations. 12s. 6d.

Correlates structure and function, and emphasises the essential inter-dependence of Anatomy and Physiology.

A TEXTBOOK OF BIOCHEMISTRY

By A. T. CAMERON, D.Sc.,
F.I.C., F.R.S.(C)

Professor of Biochemistry, Faculty of
Medicine, University of Manitoba.
New (5th) Edition. 3 Plates and 23
Text-figures. 15s.

This edition has been almost completely rewritten, and large sections have been rearranged. Includes several new illustrations.

THREE RECENT BOOKS

A SHORT TEXTBOOK OF SURGERY

By C. F. W. ILLINGWORTH,
M.D., F.R.C.S.(Ed.)

Lecturer in Clinical Surgery,
University of Edinburgh.

8 Plates and 179 Text-figures. 21s.

"It covers the whole field of surgery and should prove invaluable to the student as the important and common surgical conditions are dealt with 'in extenso' . . . will take its place as one of the really valuable books which students require."—THE MEDICAL PRESS.

A SHORT TEXTBOOK OF MIDWIFERY

By G. F. GIBBERD, M.S.,
F.R.C.S., M.C.O.G.

Assistant Obstetric Surgeon,
Guy's Hospital.

187 Illustrations. 15s.

"The author and publishers deserve the greatest possible praise for this work, which is of a practical character, illustrated by excellent photomicrographs and fine drawings. . . is undoubtedly one of the best books available on the subject of modern midwifery."

—THE PRACTITIONER.

DISEASES OF INFANCY AND CHILDHOOD

By WILFRID SHELDON,
M.D., F.R.C.P.

Physician for Diseases of Children, King's
College Hospital.

New (2nd) Edition. 125 Text-figures and
13 Plates. 21s.

"This book should appeal not only to medical students and practitioners, but to all those interested in children's diseases. . . it may be looked upon as being the most up-to-date treatise of diseases of children."

—THE MEDICAL PRESS.

104 GLOUCESTER PLACE, LONDON W.1

A NATIONAL SERVICE TO MOTHERS.

W. & T. Avery Ltd., Soho Foundry, Birmingham, offer a baby weigher for hire at the convenient terms of 4/- per month (minimum five months).

In cases where test feed weighing is essential for a delicate baby, Medical Practitioners cannot do mothers a better service than to draw their attention to this convenient scheme.

Mothers should be advised to write direct to "Avery, Birmingham."

HENRY KIMPTON'S PUBLICATIONSNEW (SECOND) EDITIONTHIS DAY**A TEXT-BOOK OF HISTOLOGY**

Functional Significance of Cells and Intercellular Substances.

By E. V. COWDRY.

SECOND EDITION. ENLARGED AND REVISED.

Large Octavo, 600 pages, illustrated with 323 Engravings, some in Colours.

Price 31s. 6d. net. (Postage 9d.)

Cloth.

The book is no ordinary compilation but rather a mine of authoritative, up-to-date information and interpretation.

NEW (EIGHTH) EDITIONNOW READY**PHYSIOLOGY IN MODERN MEDICINE**

By the late J. J. R. MACLEOD, M.B.

Edited by PHILIP BARD.

Professor of Physiology, Johns Hopkins University School of Medicine.

EIGHTH EDITION. REVISED AND RE-WRITTEN.

Royal Octavo, 1,086 pages, with 355 Illustrations.

Price 36s. net. (Postage 9d.)

Cloth.

In this new edition the present editor has followed a practice adopted by Prof. Macleod. Each major division is the work of a writer who is actively engaged in the study of the subject he treats. The greater part of the book has been entirely re-written.

NEW BOOK**CAUSE AND PREVENTION OF DISEASE**JUST OUT

By WILLIAM HARVEY PERKINS, M.D.

Royal Octavo, 713 pages.

Price 35s. net. (Postage 9d.)

Cloth.

This work is an important contribution to the practice of preventive medicine. The author has systematized what is known of the causes and origins of disease, and has supplied the material that embraces all that is required for an inclusive view of the etiologic factors of disease and ill health, clarifying and enlarging previous conceptions.

A NEW BOOK**PEDIATRIC DIETETICS**NOW READY

By N. THOMAS SAXL, M.D., F.A.C.P., F.A.A.P.

Royal Octavo, 565 pages, with 57 Engravings and 2 Coloured Plates.

Price 32s. net. (Postage 8d.)

Cloth.

"Will be found of considerable help to the practising paediatrician."—*British Journal of Children's Diseases*.NEW WORKJUST OUT**PRACTICAL OTOTOLOGY, RHINOLOGY AND LARYNGOLOGY**

By ADAM EDWARD SCHLANSER, M.D.

Royal Octavo, 315 pages, with 31 Engravings.

Price 21s. net. (Postage 6d.)

Cloth.

It is the purpose of this book to show how each of the complaints that occur in oto-rhinolaryngological practice may be handled expeditiously and successfully. To this end the book has been made distinctly clinical and its instructions may be followed with certainty, confidence, and ease.

DEATH CHART of FOGGY DAYS

This graph and its legend are taken, by permission, from a new booklet, 'Britain's Burning Shame', published by the National Smoke Abatement Society. In view of the importance of this book copies have been made available free at your Gas Showrooms. The booklet tells the whole horrible story of domestic smoke and the damage it does inside and out.

70% of a city's fog and grime come from home chimneys burning old-fashioned raw fuel. City fogs bring more disasters than head-on crashes, loss of business and jokes in the humour pages of magazines. They bring death to the sick and old. Sudden death to lung sufferers who would otherwise have seen the summer again.

Fogs are brought on by certain weather conditions. But city fogs are composed at least 70% of soot and grime from home chimneys—chimneys burning old-fashioned smoke-making fuel. Every smoking home chimney is adding to the 'aerial sewage' of England, increasing by ever so little the ill-health of the country.

Can't something be done? Yes, it is being done, slowly. Every time someone decides to do away with an old-fashioned smoke-making fire in his house and burn a smokeless fuel (such as gas or coke), it means an

extra minute, perhaps, of sunshine somewhere. Gas and Coke are working miracles to make homes clean inside. Eventually there will be a national miracle of an air fit for children and old people to breathe. Gas and coke will have helped to bring that miracle to pass.

Where you want warmth quickly, for short periods—a gas fire! Choice of many colours. It ventilates a room automatically.

NO
SMUTS
NO
SMOKE
WITH

The open coke fire burns without smoke. Saves 2d in the 1/- on your fuel bills. Gas-ferried. Very convenient, very modern.

GAS AND COKE

The fuel of clean homes and clean cities

★ The above facts and many others as to the injurious effects of smoke may be found in publications of the National Smoke Abatement Society, Chondos House, Buckingham Gate, London, S.W.1. By joining the Society, which is an independent body, you will keep up to date and help the campaign for cleaner cities.

Issued by the British Commercial Gas Assoc., Gas Industry House, 1 Grosvenor Place, London, S.W.1

THE PLACE OF BRAN IN THE TREATMENT OF COMMON CONSTIPATION

WHEN dealing with a case of common constipation traceable to a deficiency of "bulk" in the diet, the first thought is naturally: "How can the daily intake of bulk most conveniently be increased?"

Fruit and vegetables, of course, supply a partial answer to the problem — but it is not infrequently found that these foods alone are not a sufficient corrective unless eaten in unappetisingly large quantities.

For this reason many nutritional authorities today advise giving prepared wheat bran in the pleasant form of Kellogg's All-Bran.

An attractively crisp breakfast cereal

All-Bran is an attractively crisp cereal which most patients find a pleasant addition to their normal breakfast menu. The fibrous bulk in All-Bran is of the same type as that derived from vegetables and fruit, but has the advantage of being less easily broken down during digestion, and its action is therefore more effective and

thorough. All-Bran is, moreover, an excellent source of both Vitamin B and iron, which add greatly to its dietetic value.

All-Bran is intended to be eaten daily, like an ordinary breakfast cereal. The great value of All-Bran is that it absorbs water like a sponge. This water-softened mass gently but effectively aids elimination. Eaten regularly, it promotes a thorough evacuation of the bowel-contents in a natural manner that gives real relief and freedom from strain.

All-Bran may with advantage be prescribed in all cases where additional bulk in the diet is indicated. It may be eaten with milk or cream or cooked into scones, bread, etc. It may also be sprinkled over salads or other foods. To assure maximum effectiveness plenty of fluid should be taken, preferably between meals. All-Bran is obtainable from all reliable grocers. A packet will be sent free on request to any qualified practitioner. Inquiries should be addressed to: Kellogg Company of Great Britain Ltd., Stretford, Manchester.

Kellogg's All-Bran is most palatable served with plenty of milk or cream. Many like it sprinkled over their favourite breakfast cereal.

SOMNIGEN

The advantage of "Somnigen" is that it does not produce the Headache, Nausea, Furred Tongue, or Constipation so frequently noticed when preparations of Opium or Morphine are administered. It contains the whole of the Alkaloids of Opium in chemical combination with Hydrobromic Acid, which assists the sedative action, and is STANDARDISED so as to contain 0.75 per cent. Morphine, but entirely free from nauseous odour and characteristic taste.

As an Hypnotic, Sedative, Opiate and Diaphoretic it has always given great satisfaction, as its action is most regular and certain, producing refreshing sleep without unpleasant after-effects.

"It is free from the odour of the ordinary Tincture of Opium, and does not produce the same disagreeable after-effects."—THE MEDICAL ANNUAL.

"It has the advantage of not being followed by nausea and headache and other drawbacks of Laudanum."—THE INDIAN MEDICAL GAZETTE.

LOCAL TREATMENT OF PSORIASIS ★

Not only does Psoriasis respond readily to local treatment with Sphagnol Peat Ointment, but the relief is lasting. Neither dangerous nor painful, psoriasis is annoying and unsightly. In cases where the correction of faults in clothing and diet brings no satisfactory response, regular applications of Sphagnol Peat Ointment prove beneficial in a very short time. Sphagnol con-

tains the soothing, healing distillates of peat. It is a natural antiseptic whose consistent use generally produces lasting relief. In case you have had no personal experience of Sphagnol, we shall be pleased to send you a clinical size sample for testing if you will write to Peat Products (Sphagnol) Ltd., Dept. B.M.J.16, 21, Bush Lane, London, E.C. 4.

OVALTINE

AN AID TO HEALTHY DEVELOPMENT

MODERN medical research makes it increasingly clear that abnormalities of form, mental defects and even permanent constitutional weakness, are often a direct result of failure to obtain in infancy a diet adequate to the physiological needs of the organism. The basic necessity, therefore, in constructing the dietary of the infant and growing child, is to ensure one that is complete in all the essential food elements.

"Ovaltine" finds one of its most valuable applications in this direction. Composed of the nutritive constituents of fresh, full-cream milk, eggs and malt, in well-balanced proportions, it supplies calcium, phosphorus, vitamins and other accessory food factors, and its regular addition to the ordinary diet of the child renders this safe and adequate.

"Ovaltine" is so delicious and easily digested that it can be prescribed with complete confidence for children of all ages. "Ovaltine" is easily prepared and is most economical.

A liberal supply for clinical trial sent free on request.

THE VACCINE TREATMENT OF PNEUMONIA

P. S. I. VACCINE

(WYNN'S FORMULA)

EVANS

The outcome in pneumonia is largely decided during the first 48 hours and specific treatment is of little, if any, value after the third day. The importance of early specific treatment whether by serum or vaccine is therefore urged.

Vaccine has the enormous advantage that it can be carried in the bag and injected without delay. True lobar pneumonia is less common in many districts than a mixed infection pneumonia, so serum is only available for possibly one-third of all pneumonias.

P.S.I. Vaccine (Evans) is made according to the formula given in the B.M.J., December 22nd, 1934, 1159, and contains in each cc:—

| | | | |
|----------------------|---|---|-------------|
| <i>Pneumococci</i> | - | - | 200 million |
| <i>Streptococci</i> | - | - | 200 " |
| <i>B. influenzae</i> | - | - | 200 " |

P.S.I. Vaccine (Evans) is issued in

| | | | | | |
|-----------------------------|-----|----------|-----|------------------------------|------|
| 1 cc. ampoules | - | - | 2/6 | 10 cc. rubber-capped bottles | 15/- |
| 5 cc. rubber-capped bottles | 8/6 | 25 cc. " | " | " | 25/- |

PRICE - 4/6 per 4 oz. bottle.
Sample and Literature on request.

Serenol is a sedative with action on the centres of the nervous vegetative system, sympathetic and parasympathetic, and on the cortical centres. Recent knowledge has shown the interaction of nervous vegetative system and endocrine system, and on this knowledge SERENOL is based. It is thus a biological, not a symptomatic, sedative, and, unlike many other sedatives, has not a direct depressant action on the cortical cerebral centres.

Serenol is indicated in conditions of anxiety and general irritability, insomnia, hyperthyroidism, hyperadrenalism (as in neurocirculatory asthenia, effort syndrome), the so-called nervous palpitations of the heart, etc.

Serenol is given in the following dosage. For mild cases one to two dessertspoonsful on retiring. For more severe cases one dessertspoonful at 10 a.m., one dessertspoonful at 4 p.m. and two dessertspoonsful on retiring.

Serenol, being a biological sedative containing no barbiturate, is not habit forming.

'A.B.' PROTAMINE INSULIN

BRAND (with zinc) SUSPENSION

Effect of Insulin without and with Protamine

The absorption of insulin injected in the form of 'A.B.' Brand Protamine Insulin (with Zinc) Suspension is much prolonged and closely resembles the natural secretion of the pancreatic islets. This insulin has a steady action and exerts a better control than that of ordinary insulin over the carbohydrate metabolism. The number of injections can be reduced, a lower total dosage is usually necessary, and the subjective symptoms of diabetes markedly improve.

IT ISN'T JUST "GOOD-FOR-YOU"

DOLE Pineapple Juice, as you can see from the analysis below, is a valuable addition to anybody's diet. It is a good source of Vitamins A, B and C and natural fruit sugars. It provides mineral salts Calcium Oxide .022%, Magnesium Oxide .019%, Copper .0002%, Manganese .0003%, and Iron .0005%. **DOLE** Pineapple Juice has an alkaline reaction in the body which tends to offset the effects of acid-producing foods. It has been accepted by the American Medical Association Committee on foods and is in constant use in many American Hospitals and Nursing Homes.

But it is equally important that this valuable fresh-fruit drink is more than acceptable to patients, especially children with obstinate appetites or fickle tastes. Its fresh tangy flavour, not like the syrupy liquid you expect to find with tinned pineapple, is refreshing, thirst-quenching and invigorating. *It is not often you come across a drink that you can recommend with such sure knowledge that your advice will be followed.*

TYPICAL ANALYSIS OF DOLE PINEAPPLE JUICE

| | | | |
|-------------------------------|--------|----------------------------------|--------|
| Moisture | 85.3 % | Titrateable acidity as | |
| Ash | 0.1 % | citric acid | 0.9 % |

WATERLOO ROAD, LONDON, N.W.2

L I V O G E N

In conformity with recent research concerning the value of the Vitamin B complex, Livogen has been modified so that it now contains in ample proportions Vitamin B₁, Vitamin B₂ (lactoflavine), Nicotinic Acid and Vitamin B₆ as well as all the blood-regenerating principles of liver.

Vitamin B₁, Lactoflavine, and probably Nicotinic Acid and Vitamin B₆, constitute part of enzyme systems necessary for the normal metabolic processes of the

cell and supply molecular groupings which the body needs but cannot synthesise.

Livogen, therefore, is the perfect reconstructive tonic inasmuch as it supplies those substances most usually lacking in the diet which are necessary for the stimulation of the processes of repair and reconstruction of tissue, and for the maintenance of normal function when restoration is complete.

'PANOPEPTON'

'PANOPEPTON' presents the entire digestible substance of prime lean beef and best wheat in a perfectly soluble, diffusible, and absorbable form. It is at once a grateful stimulant and food.

Supplied in 12-oz. bottles.

For an adult the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

PEPTOGENIC MILK POWDER

For preparing HUMANISED MILK.

Humanised Milk is easily prepared with Peptogenic Milk powder, is very palatable, being thin and sweetish like human milk. It very closely approximates to Mother's Milk, both qualitatively and quantitatively, and calls for the same digestive action on the part of the infant as does breast milk.

Supplied in two sizes.

Originated and Manufactured by—

FAIRCHILD BROS. & FOSTER (Inc. N.Y.), NEW YORK, and 65, Holborn Viaduct, London, E.C. 1.

Agents:

BURROUGHS WELLCOME & CO., LONDON, SYDNEY and CAPE TOWN.

Cadburys have perfected a
SPECIAL CHOCOLATE
which is Sugar Free and
therefore a suitable addition to
the dietary of diabetics

This chocolate is extremely palatable, and because Cadburys have unlimited facilities for laboratory research and the subsequent manufacture and marketing of such a product it sells at a very low price. Further details and analysis with a sample of this Special Chocolate will be gladly forwarded to anyone interested. Please write to Cadburys Laboratories, Bournville.

CADBURY BROS. BOURNVILLE ENGLAND

VOLPAR

The British Drug Houses Ltd. announces the issue of Volpar, a new contraceptive formulated in co-operation with the Medical Sub-Committee of The National Birth Control Association and the outcome of nearly ten years' continuous investigation conducted by University research workers under the direction of the Birth Control Investigation Committee. Laboratory tests have shown that the active principle of Volpar is the most powerful non-toxic spermicidal substance known. The product is presented in two forms:—

VOLPAR GELS

Soluble suppositories primarily intended for use alone, or (for maximum safety) with a cap or sheath. *§ They cannot withstand tropical heat, but are suitable for use in Great Britain and other temperate climates.*

VOLPAR PASTE

An ointment for the lubrication of occlusive caps and sheaths or condoms. It will withstand wide variations in climate, and is suitable even for tropical use.

VOLPAR GELS AND VOLPAR PASTE, IN ADDITION TO BEING THOROUGHLY EFFICIENT, ARE AESTHETICALLY UNOBJECTIONABLE.

GELS: in screw-capped glass tubes containing 1 dozen gels, 2s. 0d.

PASTE: in collapsible tubes containing sufficient for 12 applications, 2s. 0d.

Prices in Great Britain only

Volpar Gels and Paste are sold to the public only by pharmacists. Members of the Medical Profession are invited to apply for a booklet describing Volpar and the researches which have led to its production.

"EARLY" is the watchword in

PNEUMONIA CONTROL

PARTICULAR EMPHASIS HAS RIGHTLY BEEN LAID ON THE WATCHWORD "EARLY" for the control of pneumonia:

"Early diagnosis, early typing and early serum treatment mean early recovery."

The importance of *early typing* cannot be over-emphasised, for it not only serves to identify the specific etiologic agent of the pneumonia, but frequently, and especially in atypical pneumonias, it also aids in fixing the diagnosis and makes possible the early administration of specific serum.

The Neufeld Rapid Typing reaction should be applied to the patient's sputum immediately upon suspicion of lobar or bronchial pneumonia.

"Pneumococcus Typing Serum *Lederle*" Types 1 to 32 for the Neufeld Reaction, ready for immediate use, are available in 1.0 cc. vials and for the following combinations—

Send for Booklet—
"For the Treatment of Pneumococcal Pneumonias
Types 1, 2, 4, 5, 7 and 8—Anti-pneumococcal Sera."

- Mixture "A"—containing Types I, II and VII.
- Mixture "B"—containing Types III, IV, V, VI and VIII.
- Mixture "C"—containing Types IX, XII, XIV, XV and XVII.
- Mixture "D"—containing Types X, XI, XIII, XX, XXI and XXIV.
- Mixture "E"—containing Types XVI, XVIII, XIX, XXI and XXVIII.
- Mixture "F"—containing Types XXIII, XXV, XXVII, XXIX, XXXI and XXXII.

Decongestion of the nasal mucous membrane with "Propadrine" Hydrochloride

"PROPADRINE" HYDROCHLORIDE is specifically indicated in relieving the nasal congestion of coryza, rhinitis, sinusitis and nasal pharyngitis. Its effective yet gentle decongestive action on the inflamed and engorged mucosa promotes freer drainage and permits more normal air-volume ingress.

"Propadrine" Hydrochloride, S & D (phenyl-propamol-amine hydrochloride), is a synthetic analogue of ephedrine. Their pharmacological properties are similar, but "Propadrine" Hydrochloride is less toxic, as demonstrated by laboratory experiments confirmed in clinical practice.

In constriction of the nasal mucous membrane, "Propadrine" Hydrochloride produces prompt action and prolonged effect. Whenever a decongestive agent is indicated, it may be applied topically by saturated tampons, instillation or atomized spray.

As a bronchodilator in the control of bron-

chial spasms, Capsules "Propadrine" Hydrochloride exert a clinical response similar to ephedrine, but are usually free of the symptomatic disadvantages often accompanying the use of ephedrine such as nervousness, insomnia and motor-restlessness. For this reason, in chronic and protracted bronchial irritation, the use of "Propadrine" Hydrochloride usually obviates the necessity of simultaneously administering sedatives.

"Propadrine" Hydrochloride Products are available in the following convenient dosage forms:

Solution "Propadrine" Hydrochloride, 1%, in one-ounce bottles. An isotonic solution.

Nasal Jelly "Propadrine" Hydrochloride, 0.66%, in one-half-ounce collapsible tubes.

Capsules "Propadrine" Hydrochloride, $\frac{1}{2}$ gr., in bottles of 25 and 500. (Also used for the symptomatic control of hay fever and asthma.)

CRUNCHY FOODS

and the digestive juices

The view that the process of digestion begins in the mouth is accepted by most physicians. The importance of a free flow of saliva cannot, therefore, be underestimated.

Crunchy foods which must be masticated thoroughly before they can be swallowed, naturally increase the flow of saliva. It is generally believed that

such crunchy foods therefore reach the stomach in an easily assimilated form, and also that softer foods taken at the same time will derive benefit from the extra saliva.

For these reasons many doctors recommend patients to include Ryvita in their diet. A complimentary carton of Ryvita will gladly be supplied on request.

The Emulsion for Children

In many of the wasting diseases of childhood, a sensitive, irritable stomach and intestines preclude proper nourishment.

Under the administration of 'Angiers' these organs become pacified and retentive, digestion is strengthened, and the assimilation of food is normal and complete. It is often-times surprising how quickly pale, flabby, weakly infants and children gain flesh, strength and vitality when they are given the Emulsion systematically.

We confidently urge its trial in marasmus, scrofulosis, inherited tuberculosis, anæmia, and in the malnutrition associated with acute infectious disease. It is likewise one of the most useful and dependable remedies for the treatment of bronchitis, whooping cough and the respiratory affections associated with measles and scarlet fever.

The pleasant, cream-like flavour of 'Angiers' and its ready miscibility with milk or water, make it eminently suitable for administration to children.

A major operation in progress in the operating theatre of a London Hospital.

THE LESSON OF ANTISEPTICS

LISTER'S discovery that suppuration of wounds was caused by bacterial infection and could be prevented by the use of antiseptics opened the way to the marvels of modern surgery. To-day, it is taken for granted that every operation will be carried out without the introduction of micro-organisms into the blood.

Recognition of the importance of germ-free cleanliness, however, is no longer confined to the operating theatre and surgery; it receives ever-increasing attention from the lay public. Health standards to-day are higher than they have ever been, as a result. Naturally, elaborate precautions against infection are impracticable in everyday life, but fortunately adequate protection is provided by the liberal use of soap and water—provided that the soap is pure and has antiseptic qualities.

Wright's Coal Tar Soap has enjoyed the confidence of the medical profession for over 70 years. Leading bacteriologists advocate its use for everyday protection against infection, and it has been found that more doctors use Wright's than any other brand of toilet soap. Wright's has substantial antiseptic and antipruritic qualities, and is the only soap to contain

'liquor carbonis detergens,' the valuable skin therapeutic used and recommended by the foremost dermatologists. You can use and recommend Wright's Coal Tar Soap with every confidence.

The Appetising Four-Vitamin Malt Food

NUTRIENT PROTECTION

In a basis of good malt extract, appetisingly flavoured, Ostomalt provides four vitamins that a child needs — vitamins that are so often deficient in winter diets. Ostomalt provides vitamins A, B, D and also C—in balanced *standardised* form, together with a useful supplement of calcium glycerophosphate. Moreover, the easily digested malt extract of Ostomalt gives the 'body' to this

preparation to make it substantial fuel for growing needs. Ostomalt is most economical in use, being three times as potent in vitamins A and D as the best malt-and-cod-liver-oil product. One *teaspoonful* takes the place of three *tablespoonfuls*.

PRODUCT OF THE
GLAXO LABORATORIES

OSTOMALT

In ½-lb. jars, 1/9; in 1-lb. jars, 3/-; in 7-lb. jars, 17/-.

Prices (not applicable in Eire), are subject to usual professional discount.

GLAXO LABORATORIES LTD., GREENFORD, MIDDX. BYRon 3434

*Re Calc. Sod. Lact. gr. 7½
Calc. Phosph. gr. 2½
Vitamin D 500 i.u.
misc. Fint. Tab. (Ostocalcium)*

TO BE EATEN

Whenever calcium is indicated — be it in pregnancy or, for example, in the treatment of chilblains — Ostocalcium provides the mineral in its most *eatable* form. Improved flavour and friability make this tablet readily acceptable to patients. The doubled calcium content, now yielding 1½ grs. (0.1 gm.) per tablet, is an appreciable advantage for effectiveness and economy. Absorption and utilisation of the calcium are enhanced by the Ostelin vitamin D incorporated in ample measured amount.

Each Ostocalcium Tablet contains 7½ grs. calcium sodium lactate, 2½ grs. calcium phosphate, and 500 international units of vitamin D.

OSTOCALCIUM TABLETS

Prices (not applicable in Eire) are subject to usual professional discount.

THE STATE AND MEDICAL RESEARCH*

BY

SIR EDWARD MELLANBY, K.C.B., M.D., F.R.C.P., F.R.S.

Secretary, Medical Research Council

At no time has the position been more favourable than to-day for appreciating Harvey's greatness as an investigator or for acknowledging the extraordinary position he holds as a leader of medical science. More and more men are endeavouring to follow his example, and the revolutionary changes in medicine during the past sixty years have only increased the appreciation of his foresight and skill.

Many still living have seen this revolutionary phase of modern medicine and surgery in its entirety—the introduction of new methods of prevention, diagnosis, and treatment of disease, the enormous increase in hospital accommodation, the initiation and development of clinical laboratories and radiological departments, and the transformation and multiplication of the public health services. Most medical men will agree that the main cause of these developments is the great increase of knowledge in medical science acquired in the past sixty or seventy years as the result of investigation. People began to realize that health and disease are not conditions conferred upon man for humble acceptance, but that a certain method (Harvey's method) of acquiring knowledge is at hand, and that by this knowledge disease can be combated and death itself warded off. More men and women entered the field of investigation, and knowledge accumulated more rapidly. Success bred success. A spirit of optimism as regards the acquisition of good health and the elimination of ill-health pervaded the mind of civilized man.

It cannot be denied that in this country, and even more so in the United States of America, the increase in scientific research has had no special intellectual basis so far as the public, even the enlightened public, is concerned. Research has been found to deliver the goods in these countries often enough to deserve special encouragement. This was not the case in Germany, where for a hundred years or more it had been accepted that teaching in medicine should be done by those who could extend or had extended the boundaries of knowledge by research. It is true that great medical discoveries were made in the past century in countries other than Germany, but in such cases the researches which led to these discoveries were made by men of genius working independently and often under uncongenial conditions. Germany, on the other hand, had an academic atmosphere saturated with the research spirit. Whatever may be the present or future state of medical and other science

in Germany, we ought to remember with appreciation this enlightened attitude, which flourished at a time when medical research breathed but feebly in other countries. Nor, in these earlier times, was the outlook utilitarian. A time came, however, when it was apparent that medical research could and did forge weapons to fight disease. The discovery of antiseptics, antitoxins, and salvarsan left no doubt on this point. It came to be realized that medical and other research was not an interest of a few curious people with a special aptitude for discovering facts which seemed to have but little bearing on life. Wise men, both in public life and in industry, saw that scientific research was the life-blood of modern existence, that it was a means of providing easily the needs of mankind and the knowledge necessary for healthy existence under modern conditions. As might be expected, the earlier disinterested German attitude was first affected by the practical issues, and organized research there received even a greater fillip. Industrial leaders in Germany and in the United States of America also soon grasped the significance of research applied to industry, and found that throwing a sprat of expenditure on research to catch a mackerel of large profit was good business.

It has sometimes been said that it took the great war to make this country realize the importance of scientific research, and it is true that the Department of Scientific and Industrial Research was only set up in 1915, largely as the result of the urgent demands of war. The Medical Research Committee, however, was initiated in 1913. Practically all its activities until 1919 were directed to the solution of medical problems related to war, and right well did it justify itself.

The Endowment of Research

During the present century there have been two rapid developments in medical research activity running side by side, the one in this country and the other in the United States: the former organized and to a large extent financed by the State, the latter richly endowed and controlled by private interests. Each movement has already produced a good harvest, but the crops differ in many respects. It can at least be said that the American record of medical research during the past twenty years has been a very fine one. There is good reason to believe that in America the State intends in the near future greatly to supplement private endowment for medical research, and the recent

* Harveian Oration (abridged) given to the Royal College of Physicians of London, October 18, 1938.

Nuffield scheme started at Oxford is possibly an indication that private individuals here will in future regard the endowment of such research as more worthy of support than in the past.

Financial aid, either from the State or from private endowment, is an essential to research. Money cannot, of course, buy discoveries, certainly not great discoveries, in the same way as it can buy manual labour; but it can offer freedom from the need for earning a living by ordinary work, and afford to those with the necessary ability the means to devote their lives to research. Until recent times, scientific discovery in this country has depended only too often on the haphazard distribution of wealth. Sometimes, as in the case of Darwin, private means have allowed leisure for experiment and contemplation. Sometimes a private society, such as the Royal Institution, has endowed men like Humphry Davy and Faraday in the same way as Trinity College, Cambridge, subsidized Newton. If these men had been completely without financial resources, and dependent for their living on ordinary labour, there can be no reasonable doubt that the particular discoveries associated with their names would not have been made by them.

On the other hand, the limitations of finance to ensure additions to knowledge are equally undoubted. Some of the best work has been done by men labouring under conditions of extreme simplicity. Would, for instance, the work of Claude Bernard and Pasteur have been better had they received abundant financial support early in their lives? It is true that when their work was more or less finished both these men were given adequate laboratory facilities, but for most of their active lives, when they were making their great discoveries, they worked under very poor conditions. The Harveys, the Claude Bernards, and the Pasteurs of this world will make discoveries under the most meagre circumstances, and, beyond a minimum of amenities, increased finance and improved facilities may not aid their output—may, indeed, detract from it.

These instances from past history, where men given slight but real opportunity have made discoveries of the first order, have imbued us all with the thought that many a genius for research must have been lost to the world by lack of such opportunity, and there is a determination that in future finance will not be the preventing factor. Nothing is more clear than that the mental outlook and ability to discover are present throughout all grades of society. Whether this ability is equally distributed is not so sure. In any case, the real discoverer is a rarity in all classes of society, and it must be the object of civilized communities to find these individuals and give them the means of freely carrying out their activities. As a class, those who choose research for their life's work are unworldly in the sense that they are content with a relatively low standard of living as compared with what they could often obtain in other walks of life. It is generally true that the more able the investigator the less are his demands on life's amenities. Even so, however, there is a limit to this, and the scientific genius when found must be given his chance and not be expected to use up all his time and energy fending for a living. In addition to these men there are a larger number who, although not men of genius, work out the rich veins discovered by their leaders. These men must also be looked after and given facilities for their work.

This, then, was the great justification in this country for State support for research, since private endowment was completely inadequate. Everybody will be agreed up

to this point. In the absence of private endowment State support assures the opportunity and offers a means of livelihood to potential investigators who could not otherwise direct their activities to medical research. On the other hand, it is certain that State endowment of medical research must be associated with State control. According to general experience, such control is often repressive and is accompanied by bureaucratic methods and all that these imply. The words "control" and "bureaucracy" have a disagreeable sound in all ears, but more particularly in the ears of those searching after truth by experiment, when success depends upon freedom to work quietly. One of the main objects of this discourse is to show how State control of medical research can be brought about and be compatible with freedom to the investigator. Another object is to explain the manner in which State funds are used for the purpose of promoting discovery in medicine.

The Medical Research Council

It is now twenty-five years since the Government decided to promote medical research by setting up the Medical Research Committee under the National Health Insurance Joint Commission to administer funds provided by the National Health Insurance Act of 1911. This arrangement was terminated in 1920 when the Medical Research Council received its present title and constitution. From this time funds for its work began to be provided direct from the Treasury in the form of a Parliamentary grant-in-aid, and the Council became subject to the general direction of the new Committee of Privy Council for Medical Research, with the Lord President of the Council as Chairman.

Of the present eleven members of the Council, eight are men chosen for their scientific and medical qualifications in the various fields of medical science. Every scientific member must not only have the approval before election of the Lord President of the Council but also that of the President of the Royal Society. Only two members are politicians in the sense that one must be a representative of the House of Lords and the other of the House of Commons. At present the remaining member, the treasurer, is a distinguished banker. With a body of this nature it will be seen that direct political influence is not likely to affect their decisions. It might then be said that, although direct political influence is obviated by the constitution of the Council, some such influence might still be exerted through the secretariat and permanent officials. To meet this the Secretary of the Council is elected by the Council itself—that is, by the scientific majority of the members. The Secretary of the Council is also Secretary of the Committee of Privy Council for Medical Research. There are, in other words, no administrative officials or machinery standing between the Medical Research Council and the Lord President of the Council. So far as constitution and powers are concerned, every action has been taken to see that the Council consists mainly of a group of experts in medical research with full authority to use and control the public money placed at its disposal, independently of all other bodies.

A question that often arises calls for consideration here. Some will doubt whether it is good for medical science that any group of men, such as constitute the Medical Research Council, should be in a position to act almost as dictators in a whole branch of scientific study. It may be argued that, however able, they are apt to become for the time being a body of official interpreters of the truth and, if they are wrong, to misdirect the lines of investigation.

even the interpretation of results so as to interfere with the development of truth. The first answer is that a sure safeguard against the continuation of biased views by an authoritative body is the constant change of personnel of the Council, whose individual term of office is four years. It is, however, a most important question, and its importance is made particularly evident when medical men occasionally appeal to the Council, not for financial support so much as for moral backing of their particular views and a pontifical declaration in favour of their special solutions of problems of health and disease. It is obvious that the Council must never become a backer of any speculative views. In forwarding research the Council must clearly use its discretion, and it can only act to the best of its judgment in this most difficult enterprise.

For the most part, good work is financially supported, but occasionally other work of a more uncertain nature is given the benefit of the doubt and assisted until its true value is seen; but whether the work be good or otherwise, the results obtained, and the views expressed thereon, are those of the individual investigators and not of the Council.

There always have been, and there probably always will be, mistakes in the appraisal of some investigators and their work—cases where relatively poor workers stand, especially in the eyes of their near colleagues, on a pedestal of distinction, and the much more serious case where the first-class discoverer and his work go unrecognized. After all, it is not so long since Lister passed through ten years of criticism and obloquy before the value of antiseptics was accepted. The Medical Research Council can do something to prevent the recurrence of an incident of this kind by asking other workers to repeat the investigation which is criticized; but that is not enough, and it is necessary for all medical men, especially those not engaged in research, to be guarded in their criticisms of the discoveries of others. The critical mind is useful, however, especially when it is associated with the power of discovery. A long experience of scientific research has taught me that only seldom are the facts of a discovery wrong; but the interpretation of these facts, and especially the first interpretation, is often wrong.

This question of the appraisal of new discoveries, especially when they are of a nature which requires much time and careful inquiry for repetition, is clearly one of great difficulty. Nor, so far as the individual worker is concerned, does the matter end always with the establishment of the correctness of the discovery itself, especially if it is one of great importance, and even Harvey's reputation as a clinician was anything but raised by his discovery of the circulation of the blood. Wrong personal judgments and false values are always liable to be met with in the research field, and this is one of the strains which individual workers must expect to experience. At least it will be clear that the estimation of the relative value of discoveries and their discoveries is one of great importance to the Medical Research Council, all of whose actions in promoting research are a reflection of its judgment of men and their investigations. In my experience more mistakes of judgment are due to benevolence than to harshness, so far as the Medical Research Council is concerned.

Advisory Committees

A brief description of the mechanism and some of the general principles guiding the actions of the Medical Research Council may now be given, because there are probably many medical men interested in research who have no idea of these facts.

For general guidance, as regards much of the detailed work, the Council relies on the advice of committees specially set up to cover a large part of the field of medical science. Here, as in the formation of the Council itself, and indeed as in every problem of medical research, the question of personnel holds the key to the situation. Every person should be chosen primarily because of his capacity to aid investigation. Representation either of territory or of learned societies must be absolutely subsidiary to the main purpose of research itself. Territorial and representative interests are out of place in these committees; detailed technical knowledge and sound judgment alone are essential. Representation on committees must, if possible, be confined to representation of research in different parts of the special field of investigation, and it is always wise to have a number of active workers as well as those with past experience of research in any body whose duty it is to plan, initiate, and guide investigation into unknown territory.

The Medical Research Council has twenty-seven such committees. In addition, the Industrial Health Research Board, an important subsidiary of the Medical Research Council, receives advice and guidance from those committees whose work is primarily associated with problems of industry. Some of these committees are appointed conjointly with other bodies. All the services of the members of committees are given voluntarily, and magnificent work has been done by them. Their advice and help are absolutely essential for the work of the Medical Research Council.

Finance

Now a few words as to the finance of the Medical Research Council. Its present annual grant from the State is £195,000, having increased to this sum from about £50,000 which it received at the time of its institution as the Medical Research Committee twenty-five years ago. The block grant is considered every five years, a method which has its advantages and disadvantages. It has the advantage of allowing the Council to plan ahead with some feeling of security. It has the disadvantage of having to provide suddenly for expensive research, often at the request of other Government departments, out of a fixed income, and so curtailing the ordinary programme. It tends to lead to periods of expansion followed by periods of penury. The present time is one of penury. One year of penury in five is probably good, as it gives an opportunity for reviewing research programmes more closely and cutting out any dead wood that tends to occur. In addition to its public funds, the Council is in a position to help in the disposal of private endowments for medical research, and to do this either by directly controlling such funds or by giving advice to others who themselves hold the money. Private funds held by the Council for disposal as interest or capital amount to over £100,000, and, in addition, it receives annual sums of money for special purposes from the Rockefeller Foundation, the Dental Board, the Leverhulme Trustees, the British Empire Cancer Campaign, and the Halley Stewart Trustees amounting to £12,000. Altogether the sum at the disposal of the Council at the present time amounts to about £220,000 per annum.

There has recently been some public criticism, both in the Press and in Parliament, about the small amount of financial support provided by the State for medical research. It has been said that it is a curious anomaly that only £195,000 per annum is provided by the Government for research on disease which costs the country from 200 to 300 million pounds annually, since it is mainly by

research that the Government can hope to reduce the vast amount of sickness and the expenditure it involves. Whereas it is undoubted that much more financial provision is required for medical research, there is no reasonable doubt that in course of time this money will be forthcoming. The Treasury naturally demands that every request for an increase in research expenditure must be justified.

There are three main directions in which the Council disposes of the money. In the first place, the National Institute for Medical Research at Hampstead and Mill Hill has been established. Secondly, a rapidly growing number of research units, both clinical and laboratory, and whole-time workers at various centres in London and elsewhere are maintained. In the third place, grants are given to individual workers for specific pieces of research at many of the universities and hospitals throughout the country.

The National Institute for Medical Research

This organization was set up with the idea of doing large-scale and long-distance work requiring investigation by teams, and of a nature not suitable for university or hospital laboratories. Here, under the direction of Sir Henry Dale, the work is done in two main divisions: physiology, pharmacology, and biochemistry on the one hand, and experimental pathology and bacteriology on the other. An active subdivision of the former is endocrinology; while subdivisions of the latter include protistology and microscopy and physical methods. In addition to the above there is a Department of Biological Standards, the personnel of which is small, since every member of the staff of the National Institute is expected to contribute to this important part of the work when his special knowledge of a particular problem is regarded as essential.

The work of the National Institute has always reached the highest standard, and to recall its many triumphs would be a pleasant task, but it may be well to dwell on one aspect of it only—of particular interest to the practising doctor—which it has taken in its stride. I refer to the biological standardization of drugs.

Standardization of Biological Substances

Here it can be claimed without cavil that the National Institute has led the world and, both nationally and internationally, has rendered a great practical service to mankind. Here have been devised, are held, and are distributed standards required by the British Government for the purpose of the Therapeutic Substances Act, others for the Health Organization of the League of Nations, and some made necessary by the inclusion in the *British Pharmacopoeia* of biological assays for certain remedies. The following standards are held at the National Institute:

Antitoxins and Antisera: Tetanus antitoxin; diphtheria antitoxin; gas-gangrene antitoxin—(a) *perfringens*, (b) *Vibrio septique*, (c) *oedematiens*; staphylococcus antitoxin; anti-dysentery serum (Shiga); anti-pneumococcus serum, Types I and II. *Drugs*: Digitalis, ouabain, strophanthin, arspenamine, neoarphenamine, and sulpharsphenamine. *Vitamins*: Vitamins A, B, C, and D. *Hormones*: Insulin; pituitary (posterior lobe); oestrus-producing hormones—(a) hydroxyketonic form (oestron), (b) benzoate form (oestradiol monobenzoate); male sex hormone (androstosterone); corpus luteum hormone (progesterone).

Recently additional standards have been adopted by the Health Section of the League of Nations for four of the active principles of the anterior pituitary gland, and these will be prepared and stored at the National Institute.

In addition, the Medical Research Council maintains at the Lister Institute the National Collection of Type Cultures of Micro-organisms, so that, at any time, any doctor in the world can obtain for a nominal sum a specimen culture of almost any type of micro-organism. The value of this service is shown by the fact that 5,000 such applications were made last year. In a similar way medical men and research workers can obtain standard bacterial suspensions and sera for the diagnosis of enteric, dysenteric, brucella, and meningococcal infections from the Standards Department maintained at the pathological laboratory of Oxford University by the Medical Research Council. It will be obvious to anybody interested in the subject of biological standards that this work necessitates continuous research in the maintenance of standards, in the search for new standards, and in helping towards a solution the innumerable problems which arise during their use.

Research Units and External Staff Workers

The second line of policy is the placing of units of research in different institutions. This plan has shown great developments in recent years, and its progress is limited only by finance and personnel—that is to say, the Council is desirous of promoting further development along these lines, as it considers this is one of the most effective methods of aiding research. When such a unit is set up in any place the Council makes itself responsible for the payment of salaries and the actual cost of the research. It expects the university or hospital, however, to provide accommodation and ordinary services, and in the case of hospitals the provision of beds and nursing facilities. To ensure the success of each unit the most crucial point is the choice of a suitable director, who becomes a member of the Council's whole-time staff. Every encouragement is given by the Council to ensure that the unit is regarded with pride by its hosts, and each unit is considered to form an integral part of the hospital or university where it is placed. The following units have been established by the Council:

(1) The department of clinical research at University College Hospital; (2) the neurological research unit at the National Hospital for Diseases of the Nervous System; (3) the department of research in puerperal infections at Queen Charlotte's Hospital (with the aid of (a) the Rockefeller Foundation and (b) the Pilgrim Trust); (4) the department of bacteriology and chemistry at the Bland-Sutton Institute of Pathology and Courtauld Institute of Biochemistry, Middlesex Hospital; with the help of the Leverhulme and Halley-Stewart Trusts; (5) nutritional units (a) at the Lister Institute and (b) at the Dunn Nutritional Laboratories, Cambridge; (6) a unit of clinical research at Guy's Hospital; (7) a unit of research of mental defect at the Royal Eastern Counties Institution, Chesham; (8) a unit of research in experimental and clinical surgery at Edinburgh University and the Royal Infirmary, Edinburgh; (9) a department of statistics at the London School of Hygiene and Tropical Medicine; (10) a unit of industrial psychology at Cambridge University. Other members of the staff of the Medical Research Council are seconded in other universities and hospitals, each an expert in his own line and acting as a central stimulus to those around.

The influence of this policy on medical research at individual universities, hospitals, and medical schools is great. In some cases the appointments have been too recent to reach their maximum effectiveness, but in some of the older-established units the work has been first-class and is known throughout the world. There are still many important gaps in this programme, and the expansion of the policy will undoubtedly continue.

Research Grants

Now as regards the third part of the Council's policy—the giving of personal and expenses grants to aid research by individuals. The personal grants are temporary, and are usually limited to three years. This rule is, however, not always applied, and, so far as the Council can help, it is not allowed to end promising and successful research. In making these grants the initiative nearly always rests with the head of a laboratory or hospital in favour of some individual worker, or with the worker himself. The success of the application depends upon the individual and his choice of subject, and the kind of help, when given, varies greatly. Sometimes personal grants for whole-time or part-time work are made; sometimes money is provided for research expenses; and occasionally, in the case of more established workers, for technical assistance. It is in this part of the Council's activities that the various committees are most helpful.

It is difficult to appraise the real value of this policy. It is the side of the Council's work of which most is heard, for every grantee is expected to refer in his publications to help he has received from the Council. A review of scientific and clinical journals soon reveals, therefore, the number and nature of these grants, and it is commonly found in many particular journals that a large part of the work published has been financed from this source. On the other hand, there is undoubtedly some wastage, which is probably not surprising, since at any time about three hundred separate investigations are being thus supported.

One point ought to be realized by those interested in applications for research grants. The Council provides money to individuals and not to institutions. The reason for this is obvious, because the Council considers it essential to control the choice of the individual worker and the type of investigation. Much trouble and much criticism of the Council's activities have arisen through non-appreciation of this rule. When, therefore, institutions, such as universities or hospitals, are planning a scheme of medical research which they cannot completely finance it is desirable, if they wish for financial support, that they should consult the Council in the early stages and before the personnel are appointed. Needless to say, its advice is entirely disinterested, and help in such cases is gladly given.

After a personal or expenses grant is once made every individual is given the fullest freedom to develop his problem. He is encouraged to keep in touch with other investigators studying allied subjects, and it is the duty of the secretary to help in every way. Apart from sending in a short statement each year to be grafted into the annual report of the Council, and the return of vouchers for expenses, the grantee has absolute freedom, and his work is generally allowed to continue for three years unless for some special reason. By this time the average worker has had his chance, and, if at all successful, he qualifies either for a further grant or for one of the many fellowships established in the country, or is definitely placed in a post allowing research facilities. By this means also many young clinicians are given an opportunity both for research and to establish themselves. This interest of the Council in providing personal and expenses grants must not be viewed too narrowly in terms of discovery, but its influence as a recruiting field and as an educative process must also be taken into account.

There is one other activity of the Medical Research Council which touches this College closely and about

which it is desirable to speak. I refer to its policy of awarding travelling fellowships in research. The greater number of these are generously financed by the Rockefeller Foundation of New York, and others are paid out of the Council's private endowments. In all cases the award is at the full discretion of the Council, and each year many applications for these fellowships are received from young medical men with excellent medical and scientific records. A large number of the prominent young medical men in this country—both in clinical and in laboratory work—will be found among the past holders of travelling research fellowships.

Research for Government Departments

This part of the work is rapidly growing, and only its great importance justifies the large expenditure of the Council's resources on these investigations. Questions of health and disease in all their aspects are assuming greater prominence in the view of Government departments, and since many of these problems demand investigation and expert advice the Medical Research Council is often called upon for assistance.

It is useless to deny that the attitude of the Council towards the problems presented varies greatly, and all are not greeted with enthusiasm. Most of them require from the investigators answers which offer a practical solution of difficulties. If an effective answer to any problem can be foreseen the probability is that the work required is more of a routine nature and for that reason itself the inquiry may be unattractive. If the problem is more difficult and no immediate solution can be foreseen, the fact that an early answer is expected may make the task irksome to the investigator.

On the other hand, some of the problems raised by Government departments are greatly welcomed by the Medical Research Council because they offer entry into fields of opportunity where a rich harvest can certainly be obtained. One of these, in which the Council has gladly taken on large responsibility, is that of tropical medical research at the request of the Colonial Office. Already it has sent a number of trained workers into different parts of the tropical Empire to study various problems, and the opportunities are so great that it has also embarked on a scheme for training young men in research in tropical diseases. Quite recently it has also appointed a small number of experts to direct and co-ordinate a large nutritional survey in many colonial territories.

It is impossible, however, to deal adequately here with this aspect of the Council's work, but it can be assumed that most Government departments call on the Council for help and advice, and such calls often involve large-scale research. This phase of activity is removed from the public eye, but its value is none the less very great, and promises to be even greater in the future.

Research Supported by the Council

A few words now on the actual research supported by the Council. On the whole, although there are many exceptions, it will be seen that the Council's initiative in research is largely confined to the work of its permanent staff, while as regards grants (personal and expenses) the initiative lies with the investigators. This is a crude way of expressing the situation, because the permanent staff themselves have wide liberty of action in planning their investigations, and the initiative of the Council is only apparent

in the choice of the personnel, which depends on the merits of each member and on the subject he represents.

The Council seldom chooses particular diseases for investigation, though here again there are exceptions, and any promising line is followed up as a special problem when it offers itself. Generally the choice is of a broader nature, so as to include a group of diseases or a type of treatment of wide application or a system of physiological control. For instance, in the early days of the National Institute for Medical Research the Council decided to encourage specially the study of virus disease. A staff of workers was appointed, with Sir Patrick Laidlaw as leader. More recently the Council decided to extend its interests in endocrinology, and appointed Dr. Parkes to lead this work. Other able investigators were chosen as the undertaking developed, and now there is an energetic team at the National Institute investigating endocrinological problems from all angles and also working in close harmony with most of those engaged in research on this subject, both from a laboratory and a clinical aspect, throughout the country. The most recent decision of the Medical Research Council to develop the field of chemotherapy on a much larger scale than anything previously seen here is now well known. The reasons for this decision have received wide publicity, and I shall not discuss the matter further.

These, then, are some examples of the kind of initiative in research shown by the Council. In a sense, however, all its appointments to the permanent staff, whether at Hampstead or in different parts of the country, are examples of initiation of specific research. Posts have been made for suitable men in the subject to be stimulated, and not men appointed to established posts.

Nothing has yet been said specifically about the desire to encourage clinical research by the setting up of clinical units. It is well known that this is one of the main objects of the Council. This programme is being slowly but steadily developed. As men suitable for appointment to posts of this nature appear, more units will be set up. If clinical research is to enter into its kingdom, success in its early enterprises must be obtained, and this can only happen if first-class investigators are appointed to these posts.

It will thus be seen how it comes about that the Medical Research Council has not usually adopted the practice of making an organized attack on special diseases except when the problem has developed as part of a larger and more general investigation. It has not, for instance, made a mass attack on such important diseases as rheumatism in its many forms and cancer, although, of course, in both instances it supports a good deal of research by different individuals. It considers that it would be relatively unprofitable to spend the large part of its total resources necessary for the adequate study of these diseases at the expense of other work. Extensive *ad hoc* research on a disease like rheumatism, however important as a practical problem, is apt to be unprofitable until the master key of its aetiology or some other essential fact has been disclosed. This master key is just as likely to be discovered by the use of the experimental method over a wide field as by the direct study of a particular disease where the experimental method is hardly available at present. Much is heard about the value of team work nowadays, and far be it from me to deery this method of investigation. But the success of team work depends either on brilliant leadership or on the working out of a special line of inquiry, and this latter is usually supplied by the observation of one

individual. There is no great difficulty in arranging team work; the difficulty is to find the outstanding individual discoverer—the Harvey—to blaze the trail.

Criticism is often made of the type of medical research supported by the Medical Research Council. Sometimes it is said that this work is generally too academic and includes too many problems of biochemistry, biophysics, and physiology. These critics take the view that much more money should be devoted to clinical research and direct attack on disease. The opposing school say that more money ought to be used for the support of fundamental research and that all major discoveries in medicine come from disinterested research in fundamental medical science. The fact is, however, there is no royal road to discovery in medicine, and all we know is that the experimental method used by Harvey with such brilliant results is still the sure method for acquiring knowledge and "searching out Nature."

The Physiological Aspect of Disease

Claude Bernard took the view that all experimental medicine was applied physiology—a view which was killed at the time and for many years after by the success of the investigations of his fellow-countryman Pasteur, of Koch, and of the army of bacteriologists who followed them. When all disease came to be regarded as due to the invasion of the body by some form of *materies morbi*, the body itself was either forgotten completely or attention was mainly confined to the blood and its immunological powers. In more recent times the Claude Bernard point of view has received wider acceptance. The sooner the investigator recognizes the truth of both the physiological and the invasive bases of disease and the close interaction of these factors, the quicker will be the advance of medicine. Defence of the body against invasion by pathogenic micro-organisms represents a physiological process, and there ought to be no dividing-line between the two aspects of the subject for the wise investigator.

My predecessor, the late Sir Walter Fletcher, whose wisdom in guiding the policy and action of the Medical Research Council for the first nineteen years was exceptionally great, was strongly imbued with the Claude Bernard point of view, and played no small part in encouraging the revival of this philosophic outlook on medical research. It requires wise interpretation and tends to mislead those of narrow orthodox outlook who think of physiology in terms of the textbook. Yet there is nothing more prominently established in modern times than the success in discovery which has followed the extension of interest by the physiologist into that aspect of a problem which concerns a function going wrong—that is, its pathology. Again and again we have seen points of major physiological interest established by work on the pathological side. What would we know at present about such things as vitamins B₁, C, and D, insulin, thyroxine, cortin, liver and stomach active principles of pernicious anaemia, if experimental research had not been directed to the abnormal? Yet all these are physiological substances of the first order. Who can doubt that the physiology of the eye would be greatly extended by a knowledge of glaucoma, of the blood vessels by a knowledge of the cause or causes of hyperpiesis, of the heart by a knowledge of the causes of auricular fibrillation, of the kidneys by a knowledge of albuminuria, of the alimentary tract by a knowledge of gastric and duodenal ulcer, appendicitis, and colitis? It is probably an exaggeration to say that it is no more unlikely that a

physiological truth will come out of an experimental study of a pathological condition than that a fact of pathological significance will result from a purely physiological study. Every man working on a problem from either angle ought to be familiar with the other aspect. There has too long been a divorce between the two subjects, although this is tending to diminish. In recent years the Medical Research Council has endeavoured to help this situation by offering studentships to highly qualified young men to enter the field of experimental pathology as well as clinical investigation. The best qualification for such men is undoubtedly a good training in physiology, and physiologists in general would find a greater opportunity for essential discovery if they realized that a study of abnormality of function often offers the key to the elucidation of the normal process. Harvey himself did not confine his observations to one aspect of his problem. When necessary he called up evidence from every branch then known of physiology, pathology, and clinical medicine to support his argument.

The Future of Medical Research

And now, what can be said of the future? Short of a catastrophic change which may upset or even destroy national life, the future of medical discovery is bright. Past experience shows that, whatever problem concerning the body can be formulated by the human mind, there is a possibility of a solution or partial solution to it being obtained. There is thus no doubt that more and more knowledge will be obtained, giving control, both preventive and curative, of disease. The limiting factor in this progress will always be the men of genius available who make the first-class discoveries, but it is probable that with the spread of educational opportunities to poorer people more of these men will present themselves. The money available for medical research will increase, and financial obstacles will almost certainly be removed as the work develops now that the State has put its hands to the plough. No insurmountable difficulty may be expected in the direction of finance if the situation is handled wisely.

The difficulty I foresee is not that of obtaining knowledge but of its application to human needs. Curative remedies as they appear will, as in the past, undoubtedly be generally taken up by the medical profession. Much of the new knowledge to be gained, however, may concern the prevention of disease, especially the prevention of chronic and degenerative conditions, including cardiovascular disease, rheumatism, and pulmonary disease. The adoption and application of this knowledge will generally depend on the degree of education and wisdom of individuals. In some cases it will involve Government action. Without an enlightened public opinion the average individual will do nothing to save himself or herself, and the State even less. If we are to continue as a successful democracy, dependent on public opinion for action, this must be guided suitably and quickly in problems of health as in other matters.

It seems to me that one of the most important functions of this Royal College in the future will be to lead public opinion and to guide State departments, especially in matters of preventive medicine. The Royal College of Physicians is an ideal body for giving guidance and to press for action, if such be needed, in cases where scientific discovery has supplied new knowledge of importance to public health. Its independence and freedom from political relations, and the high and honourable standing

of its Fellows, would give its edicts an unassailable power.

I have now completed my task of giving a bird's-eye view of the modern movement of State support for medical research. It would be idle to pretend that the State or any other body could do much more in this matter than supply facilities to assist generally, and guide the natural genius of the country in studying problems relating to health and disease. Much remains to be done to improve and develop the movement, but, bearing in mind the limitations of any such enterprise, it will probably be agreed that the entry of the State into this field of discovery has been both stimulating and fruitful.

SOME ASPECTS OF RECENT WORK ON THE BACTERIOLOGY OF RHEUMATISM*

BY

H. J. GIBSON, M.D.

Pathologist, Royal National Hospital for Rheumatic Diseases, Bath

Reviews of the rheumatism problem appear with a regularity which is certainly not in keeping with the rate of advance of our knowledge of the subject, for rheumatism in its diverse forms presents an aetiological problem which is among the most difficult that medicine now faces. Consideration of its complexity suggests that entirely new conceptions of the host-parasite relationship may have to be evoked before the observed clinical, pathological, bacteriological, and serological results can be resolved into a comprehensive pattern.

For present purposes it is proposed to discuss the more recent work in its bacteriological and serological aspects, picking out certain salient and significant observations for more detailed consideration. As a starting-point the now well-known phenomenon of throat infection with *Streptococcus haemolyticus* followed by a latent period, which is in turn succeeded by an attack or relapse of acute rheumatism, will be considered. (Schlesinger, 1930; Collis, 1931; Sheldon, 1931; Coburn, 1931.)

Each phase has received careful study by Coburn (1932, 1935, 1936). The initial throat infection is often of very mild type, causing a slight rise of temperature, and in many cases it is overlooked by the patient. The presence or absence of tonsils does not affect the outcome, since a pharyngitis or nasopharyngitis clinically recognized as a febrile cold may be the starting-point for the rheumatic attack. Coburn and Pauli (1935d) have studied the characteristics of those strains which may be effective in producing a rheumatic relapse in susceptible subjects, contrasting them with strains which are non-effective in this respect. The effective strains were characterized by the capacity to produce strong erythrogenic toxins and haemolysins, and were in fact indistinguishable from scarlatinal strains. Those strains lacking in exotoxin production, although of human Group A and culturally similar to the effective strains, were not associated with rheumatic relapse. The toxins produced were not regarded as causative of the rheumatic lesions. On the contrary, a very low incidence of Dick-positive reactions was found among rheumatic children, and the erythrogenic toxin is

* Read in opening a discussion in the Section of Pathology, Bacteriology, and Immunology at the Annual Meeting of the British Medical Association, Plymouth, 1938.

probably neutralized as it is produced. The significance of exotoxin production appears to be as an indication that the organism is able to elaborate other soluble antigens. It may be that some hitherto unrecognized component is the effective agent in producing the rheumatic lesions.

The Latent Period

The latent period may next be considered. This may be very short, in which case the rheumatic attack follows at once on the respiratory infection. In the majority of cases the interval is from seven to twenty-one days, after which onset of fever, with increased sedimentation rate and development of clinical signs and symptoms, ushers in the rheumatic attack.

Studies have been made of the serological changes during the latent period. The antibodies found include precipitins reacting with protein fractions and antistreptolysins. In their earlier studies Coburn and Pauli (1932c) found that in normal individuals who contracted haemolytic streptococcal infection a slight concentration of precipitin appeared about four weeks after infection in the absence of rheumatic sequelae. In cases where rheumatism followed, the precipitin reaction was more definite. Schlesinger *et al.* (1935) have also noted this. They considered that the antibody-producing mechanism of rheumatic patients appeared to react more strongly to acute streptococcal infections than that of the non-rheumatic. They noted that the antibody content of the patient's serum was at its height just when a relapse was to be expected. Turning next to the anti-haemolysin, an antibody which is susceptible to accurate titration, we find similar results. Taking first non-rheumatic individuals, Coburn and Pauli (1932c) found that patients acutely ill with haemolytic streptococcus infection showed no change in titre but that a marked rise occurred during convalescence.

The same authors (1935f) confirmed this in rheumatic children. They showed clearly that in a group which developed rheumatic attacks the antistreptolysin titre rapidly rose to reach its maximum two to five weeks after the infection. On the other hand, failure to find a rheumatic relapse was associated with little or no rise of antistreptolysin titre even though the infecting organism possessed all the characters of an "effective" strain. They concluded that the greater the antibody response the more severe was the accompanying attack. As a corollary to this they suggested a conception of rheumatic disease as being the result of the following sequence: (1) infection with toxin-producing strains which initiates a process peculiar to rheumatic subjects; (2) antibody response, associated with (3) release of a substance, presumably from the antibody-producing tissues, which is toxic and which directly or indirectly alters mesodermal structures.

Coburn (1936) suggested that the rheumatic subject is characterized by a delayed development of antibodies. The evidence on which this conclusion is founded is not altogether clear. Thus in scarlet fever without rheumatic complication the maximum titre was found within seven days, while two cases of streptococcal infection with rheumatic relapse are quoted which showed a maximum on the twelfth and nineteenth days respectively.

Referring to the fact that some cases of pharyngitis are followed by rheumatism while others are not, Coburn stated:

"In both types of subjects immune responses vary widely in degree, occasionally failing to appear. When antibodies develop in the normal subject they are not associated with disease, but the development of an immune response in

rheumatic subjects is frequently accompanied by the appearance of rheumatic activity."

In view of these facts, with which most workers are in agreement, the only proof that a delay in antibody response is characteristic of rheumatism would appear to be a statistical one. It must be emphasized that delay does not imply deficiency, since the response was maximal, and increased progressively, in the more severe cases, and fall of antibody did not occur till after the disease had become clinically quiescent.

Persistent Infection by Haemolytic Streptococci

The presence of antibodies to high titre in the serum of cases of acute rheumatism irrespective of a history of *Strep. haemolyticus* infection has been amply corroborated by Todd (1932), who was instrumental in demonstrating the antigenic properties of streptococcal haemolysin, and by Myers and Keefer (1934); while Hadfield, Magee, and Perry (1934) have shown that the antifibrinolysin response follows a similar course. In association with the very definite epidemiological relation between haemolytic streptococcal infection and initial attacks of acute rheumatism as shown by institutional outbreaks (Bradley, 1932; and others), this serological evidence strongly suggests that a persistent infection with that organism is an important factor. That it is operative in every case is difficult to disprove, because the period during which the organism may be found on the respiratory mucosae is known to be a short one.

Failure to elicit a history of sore throat may be explained by the mildness of the condition, which is indeed a very characteristic feature of the prodromal infection. Thus we (Gibson and Thomson, 1933) were able to secure a history of respiratory infection within the three weeks preceding the attack in only 27 per cent. of the 119 rheumatic cases investigated in Edinburgh. As illustrating how extraneous circumstances may influence such an investigation, a year later over sixty post-scarlatinal rheumatic cases were treated in the hospital in which our series was studied. Thus a similar investigation on cases from the same population in the same hospital one year later would have produced an entirely different impression. Shapiro (1935) also could find no evidence that respiratory infection preceded the rheumatic attack in any large proportion of cases. Colds, sore throats, scarlet fever, and otitis accounted for only 30 per cent. of his cases. In 45 per cent. the onset was gradual without any evidence of infection. That writer records a number of instances where injury was followed by acute rheumatism after a latent period of some days. Wilson *et al.* (1934) from a study of convalescent rheumatic cases obtained evidence that did not support the conception of a specific aetiological relationship between respiratory infections and rheumatic fever in children. Thus less than 10 per cent. of the rheumatic attacks were preceded within three weeks by a respiratory infection. They further reported that two-thirds of the subjects experiencing rheumatic activity unassociated with respiratory infections did not exhibit a rise of antistreptolysin titre.

The failure of infections other than haemolytic streptococcal ones to activate rheumatism has been noted by Coburn (1931) in the case of pneumococcal infection and Coburn and Pauli (1935b) in the case of influenza and chickenpox. Bland and Duckett Jones (1935), on the other hand, have reported pyelitis, herpes zoster, and a febrile reaction to the Schick test as being activating factors. They are also able to show repeatedly the phenomenon of latent period followed by relapse after the intravenous injection

of T.A.B. vaccine. Operations and accidents were found by these authors to act in the same way. Thus haemolytic streptococcal infection may not be the only activating factor. Conversely, haemolytic streptococcal infection in erysipelas does not appear to be capable of initiating the rheumatic process. This is indicated by Keefer and Spink (1937), who showed that the strains responsible were mainly toxigenic, with all the other attributes of "effectiveness" in the sense of Coburn. The immune response was also shown to be efficient by the rise of antistreptolysin and antifibrinolysin in the blood, and a marked delay in the fall of the former was noted.

To sum up, epidemiological and serological findings taken together provide a striking mass of evidence in favour of the aetiological relation of the haemolytic streptococcus to acute rheumatism. Contrary evidence gathered from sporadic cases, which by their nature are not susceptible to bacteriological study in the pre-rheumatic phase, is much less convincing; but the possibility cannot be ignored that there may be a group of cases which arise without a preceding acute haemolytic streptococcal infection. Such cases may be overlooked entirely if such infections, epidemic or sporadic, are made the starting-point for the collection and study of rheumatic cases, in all of which there will naturally be serological residua in the form of specific antibodies.

Theories of Aetiology

The full interpretation of these results is admittedly impossible. Rather they enable us to discuss hypothetical mechanisms by which the rheumatic response may be produced. Two alternative theories appear to fit the observed facts. Either the disease is an infection with *Strep. haemolyticus*—and this includes the possibility of chronic systemic infection of a type not now recognized—or some other specific rheumatic agent is primary and the streptococcus is to be regarded as merely one of a number of secondary inciting causes.

Theory of Chronic Haemolytic Streptococcal Infection

Direct evidence of this is slight. Organisms isolated from the blood, joints, and elsewhere have been mainly non-haemolytic types (Póynnton and Paine, 1913; Clawson, 1925; Cecil, Nicholls, and Stainsby, 1929), and reports of such bacteriological observations are conflicting. In this connexion there are two circumstances which should be mentioned. First, the latent period allows time for the development of antibodies, and the *in vivo* culture medium of persisting organisms may become antagonistic to survival in their original form. The conditions are, in fact, those used artificially to enforce dissociation of other bacteria into variant forms. Secondly, in gonococcal infection of joints it is often found that the blood and joint fluid are sterile. This has been emphasized by Myers, Keefer, and Holmes (1934), who found, even in acute cases, that isolation of the organism from the joint fluid was only possible in 25 per cent. of cases. They concluded that the inflammatory reaction in cases with non-infected fluids is below the surface of the synovial membrane and in the periarticular tissues. They compared the non-infected effusion to that sometimes found in the pleura in pneumonia, the aseptic meningitis of extradural or brain abscess, and the sterile effusions in joint cavities in osteomyelitis. For these two reasons the failure to find organisms or the finding of types differing from those of the respiratory tract is not conclusive evidence against a generalized low-grade infection.

The failure to find bacterial products of primary toxicity has led to the theory of allergy, in which the specific element of the process is transferred to the tissues, the bacterial substance involved being an antigen of no primary toxicity, possibly derived from any of a number of bacterial types. The acceptance of this theory presupposes that we know all regarding the pathogenic potentialities of the streptococcus and that this knowledge will not explain how chronic infection with that organism could cause disease of the rheumatic type by the well-recognized modes of invasion or toxin production. Such an assumption is not justified. Within the last few years we have learned of antigenic haemolysin, fibrinolysin, capsule production as a general phenomenon among haemolytic strains, the Lancefield groups, and the Griffith types, and much evidence has been given that Dick toxin is manifold in its structure and perhaps also in its works. The antibody response so characteristic and of such a marked degree and duration in acute rheumatism may simply be an indicator of the diffusion of other exo-products possessing specific toxicity which have yet to be defined. Recent work on the multiple toxins produced by *B. welchii* and their specific effects in a variety of animal diseases is an instructive analogy.

The allergic or hyperergic variant of this theory has recently acquired support from the histological and experimental studies of Klinge (1936) and others, and merits further comment. It has been stated in its most recent form by Swift, Moen, and Hirst (1933) as follows:

"The primary haemolytic streptococcus infection is followed quickly by a state of antitoxic immunity, in contrast to a relatively delayed type-specific antibacterial immunity, and a state of bacterial hypersensitivity (hyperergy to streptococci) is concomitantly induced. With the development of partial immunity, the persisting streptococci are reduced to a state of relative avirulence for the individual, but continue to be active in the tonsils, lymph nodes, sinuses, and other tissues, where they set up focal infections, which are ideal sites for the further continuous stimulation of a hypersensitive state of the entire body. Moreover, the persistence of streptococci in these foci results in the elaboration of poisonous substances, either from the bacterial bodies or from the patient's tissues, or from both, which irritate and damage certain portions of the hypersensitive mesenchymal system."

In this form the allergic sequence resembles closely the phenomena which constitute chronic infection—for example, in syphilis or tuberculosis, where late manifestations are undoubtedly coloured by allergy. In such chronic infections the antigen circulates in the form of whole organisms capable of multiplying at the fresh sites of involvement. In rheumatism the suggestion is that bacterial products carried by the blood stream are the active agents producing similar widespread tissue changes without actual metastatic infection.

The hyperergic reaction probably has a place whatever the nature of the primary infecting agent, and is an important field of investigation which will certainly lead to a fuller understanding of the pathogenesis of the disease. The allergic conception of acute rheumatism was originally derived from the analogy between the latent period common to that disease and serum sickness. Schlesinger *et al.* (1935) have, however, pointed out that the same interval is noted between the initial infection and frankly septic complications such as otitis, meningitis, and adenitis, which are not regarded as allergic in any of the many senses of that term. Acute glomerulonephritis occupies an interesting position because it follows streptococcal infection after a latent period and a high serum antistreptolysin titre is of frequent occurrence (Seegal and Lytle, 1933; Coburn, 1933).

A final word may be said on the therapeutic evidence bearing on the relation of *Strep. haemolyticus* to acute rheumatism. Coburn and Pauli (1935c) found that active immunization with Dick toxin neither prevented streptococcus infection nor inhibited the development of the rheumatic process. Passive immunization with serum did not modify the rheumatic relapse and possibly increased its severity. Sulphanilamide has been shown by Swift *et al.* (1938) to be definitely harmful in cases of established rheumatism. Under its influence in certain cases the pulse was more rapid, pyrexia increased, fresh joints became involved, nodules appeared, and pancreatitis developed. There was no evidence that antistreptolysin production was influenced, and, on the contrary, rising antibody curves were noted after administration of the drug.

Swift points out that such incidence has no real bearing on the hyperergic theory because sulphanilamide is known not to be effective in chronic infections. Eason and his co-workers (1934, 1937) reported favourable results after the administration of large doses of scarlatinal antitoxin in established cases, but regard the effect as partly non-specific. Taken as a whole the therapeutic evidence does not support the streptococcal view-point, though it does not disprove it.

Theory of a Specific Rheumatic Infective Agent

The alternative of a specific rheumatic infective agent, possibly of virus type, is an almost equally satisfactory explanation of the facts as we know them. Such an agent might infect in childhood some 5 to 10 per cent. of the whole population. It would be characterized by latency, its presence only becoming clinically manifest when some incident such as infection (most frequently perhaps with haemolytic streptococcus), operation, or accident causes the balance of the symbiosis to be upset in favour of the parasite. This would account for the incidence of apparently new cases of rheumatism following outbreaks of scarlet fever or haemolytic streptococcal respiratory infection in about 10 per cent. of those attacked. That the rheumatic process may remain latent throughout life is shown by those cases which come to necropsy with scarred valves in the absence of any clinical history of rheumatism. It may be argued that the intense and prolonged antibody response to the exo-antigens of the streptococcus may be incidental and related to the inciting factor rather than to the primary cause of the disease. The rising curve of antibody titre extending over the whole period of rheumatic activity is, however, difficult to reconcile with this view. It may be noted that the persistence of the antitoxin giving rise to the Dick-negative state after scarlet fever is not considered to be due to continued activity of the streptococcus, and the same may be true of the antistreptolysin. There is, then, much to be said in favour of a specific rheumatic micro-organism or virus. The work of Schlesinger, Signy, and Amies (1935), Coles (1935), and Eagles, Evans, Fisher, and Keith (1937) along these lines is interesting, and forms a valuable positive contribution to the observed phenomena of rheumatism.

Obviously no conclusion is possible at this stage. Each theory which has been put forward conflicts to a greater or less extent with the available evidence. The problem may be restated but not answered.

Rheumatoid Arthritis

The relation between acute rheumatism and rheumatoid arthritis is a subject of much controversy. Clinically

there is little similarity, but on the pathological side there is a good deal of evidence that the two diseases may be aetiologicaly related. One may perhaps recall that erysipelas and scarlet fever are separate diseases which show little clinical relationship and yet possess in common an identical ultimate bacterial cause. For a discussion of this question the reader is referred to the review by Dawson and Tyson (1935), in which a great deal of evidence is collected. Poynton (1938) deals in a similar way with the whole group of "rheumatisms."

With regard to rheumatoid arthritis it is proposed simply to mention one aspect of recent evidence, the demonstration of serum antibodies to the haemolytic streptococcus.

Cecil, Nicholls, and Stainsby (1931) reported the isolation of haemolytic streptococci from the blood and joints of a high proportion of cases of rheumatoid arthritis, and the agglutination of the strains by the patients' sera in high dilution was shown by Nicholls and Stainsby (1931). The isolation of the organism has been confirmed by some but not by other later investigations, but the agglutination reaction has been demonstrated by practically all who have repeated it.

The titres reached, up to 1 in 10,000 or more, and the duration of the response are far in excess of those associated with acute haemolytic streptococcal infection. Dawson *et al.* (1932) have studied the reaction closely. They reported that the agglutinins in their thermostability and increase with the age of the subject resemble the natural antibodies of normal sera rather than the immune agglutinins following immunization or infection. They are extremely wide in their valency, and practically any haemolytic streptococcus of human group A may be used to elicit the reaction, although some strains give a higher proportion of reactors than others. The antibodies produced are thus not specific for any typical strain of rheumatic origin, as was at first suggested by Nicholls and Stainsby (1931). They were found, indeed, to react also with *R. pneumoniae*, although the type of agglutination was different in certain respects. The reaction showed no parallelism with the plasma and serum protein changes which are so pronounced in rheumatoid arthritis and which account for the increased sedimentation rate. They did, however, show a considerable but not complete correspondence with the precipitin content of the serum when tested with protein and carbohydrate antigens of *Streptococcus haemolyticus*. The antistreptolysin and antifibrinolysin of rheumatic fever are not found in rheumatoid arthritis (Stuart-Harris, 1935; and others).

Levinthal (1938) has repeated this work at the Royal National Hospital for Rheumatic Diseases, Bath. Taking a strain of haemolytic streptococcus quite at random (Group A, Griffith Type 3) from the throat of a rheumatoid arthritis patient, and examining sera "blindfold"—that is, without any knowledge of the clinical condition present—he has found agglutinin in 71.5 per cent. of cases of rheumatoid arthritis, the reaction being strong in 51.3 per cent. His figures agree closely with those of Nicholls and Stainsby (1931), Dawson *et al.* (1932), Cox and Hill (1934), Blair and Hallman (1935), and McEwen *et al.* (1935). The reaction was negative in all but a very small proportion of other clinical types of chronic rheumatism. Of particular interest is the fact that cases of ankylosing spondylitis, by many regarded as a specialized form of rheumatoid arthritis, gave the reaction in only a very few cases. He has extended the work to a comparison of the agglutinins of joint fluid with those of blood. The observation has been made that there is a group of cases in which the test is positive in the fluid and negative in the blood serum. Out of eleven serum-negative cases eight showed positive reactions in the joint fluid.

It is argued that such joint-fluid antibodies could only have arisen from a local source—the disintegrating tissue of a joint—and that such a distribution (presence in tissue, absence in serum) is that associated with sensitization. The antigen continuously discharged from a focus of infection is unchecked by circulating antibodies and

reaches the tissue cells, where it reacts with their antibody, leading to a local anaphylaxis; the so-called hyperergic inflammation. Levinthal suggests that the basic lesion is a debility of antibody-forming mechanism which does not permit of that prompt response necessary for effective disposal of infection. He regards the micro-organism merely as a source of antigen, the streptococcus being operative in some 90 per cent. of cases, while other bacteria may be responsible in the remainder. Dawson *et al.* (1932) have shown that the formation of serum agglutinins in rheumatoid arthritis is a very slow process, requiring months of active disease before high titres are reached. He and many others have observed that the titres tend to fluctuate in a remarkable way on repeated tests. Following Levinthal's views, such periods of intermission would leave the tissues vulnerable to attack.

It will be noted that the evidence is explicable by a hypothesis which is essentially similar to that of Swift in the case of rheumatic fever. It assumes that the agglutinins are true immune antibodies, and their presence is accepted as evidence of the continued presence of the streptococcus, although Dawson *et al.* (1932) suggest that neither assumption is fully justified on available evidence. Again, the fluctuating serum titre may recede, leaving antibody temporarily locked in the joint fluid, a circumstance which would explain the combination of "serum negative; joint fluid positive" upon which the theory is based.

Space does not permit of any further consideration of the great mass of recent work on chronic rheumatism. Hench (1938) has examined the evidence critically, and concludes as a clinical investigator that it still remains to be proved that the disease is infective in origin; as a practising physician he has committed himself with reservations to the microbe theory. This is a perfectly accurate summing-up of the present unsatisfactory position. From epidemiological considerations we may be fairly certain that acute rheumatism is infective; even this is denied us in the chronic forms. But the present revival of interest in rheumatism must in the near future produce results which will do something to remove this uncertainty.

ALCOHOL INJECTION IN INOPERABLE MALIGNANT GROWTHS OF THE JAWS AND TONGUE

BY

WILFRED HARRIS, M.D., F.R.C.P.

Consulting Physician, St. Mary's Hospital; Physician to the
Maida Vale Hospital for Nervous Diseases

Carcinoma of the tongue and malignant growths in the facial bones, especially in the antrum, maxilla, and nasopharynx, whether they are called sarcoma, carcinoma, or endothelioma, are in the first instance naturally the affair of the general or of the ear, nose, and throat surgeon. Sometimes one of these cases in the initial stages presents itself as a case of neuralgic pain in the face, and there may be no clear localizing signs of growth. In this way I have seen early a few cases of nasopharyngeal growths, tumours of the bones of the base of the skull, and even antral growths invading the maxilla, though the obvious evidences of antral opacity in these latter should have been sufficient to side-track such patients from a neurologist.

It is not, however, of the early diagnosis of these difficult cases that I wish to write, but rather to draw attention to the terrible pain that many of these patients suffer in the later stages, perhaps after an excision of half the tongue or of the maxilla, or after treatment of a nasopharyngeal tumour by x rays, radium bomb, or radium needles. I have yet to see a nasopharyngeal malignant growth cured by surgical removal, and though radium treatment may cause temporary disappearance of the growth and great amelioration of the symptoms, yet recurrence after the lapse of a few months is the rule, and further treatment on the same lines is useless as the new growth now appears to be radium-fast.

When the surgeon in charge has decided that no further treatment can arrest the growth, it is then essential to render the remainder of the patient's life as bearable as

possible, and only too often analgesic tablets and finally morphine injections are considered the sole remedy.

It is in just these cases, where the malignant growth is invading the territory of the fifth cranial nerve, and where the growth has not spread into the neck or ear, that destruction of the Gasserian ganglion, and perhaps of the glosso-pharyngeal nerve also, may arrest the pain completely and give the patient comparative ease and comfort.

Illustrative Cases

From my case books I have picked out seven cases of malignant growth of the maxilla and antrum in which surgery failed to arrest either the growth or the pain, and in which alcohol injection of the Gasserian ganglion gave complete relief.

Case 1.—A woman aged 36 was sent to me by a surgeon in February, 1919, after he had removed the right maxilla for a malignant growth which had been causing severe constant pain for twelve months. As the pain was in no way lessened I injected the right Gasserian ganglion with alcohol by the lateral route, causing total trigeminal anaesthesia of all three divisions of the nerve. The pain was arrested at once, and ten days later the anaesthesia remained unaltered and there had been no return of pain.

Case 2.—A woman aged 65 had suffered for two years from pains in the left cheek shooting up the temple and across the cheek, and more or less constant. There was a perforating ulcer in the left palate posteriorly, and paresis of the left external rectus muscle. Hyperaesthesia to the scratch of a pin was noticeable over the whole left trigeminal area, though she stated that the left upper lip felt "rubbery." She was referred to me by an ear, nose, and throat surgeon in August, 1932, for alcohol injection, which I did, injecting the outer two-thirds of the Gasserian ganglion by the lateral route, with complete relief of the pain.

Case 3.—A man aged 70 was sent to me in November, 1933, by a surgeon for inoperable malignant growth of the right cheek and maxilla, causing intolerable shooting pains in the territory of the second division of the fifth nerve. The cheek was so seared and tender that I used the lateral route in preference to the anterior for injecting the ganglion. It proved to be quite easy, taking only a few minutes to complete, and total trigeminal anaesthesia persisted. The neuralgic pains were at once completely relieved.

Case 4.—This patient, a man aged 52, was sent to me in June, 1936, by the same surgeon as in Case 2. He had complained for the past two months of severe pain in the left cheek, which was swollen and very tender. There was no anaesthesia of the face, though the skin was much mottled and atrophic on both sides following x-ray treatment for syphilis years before. Injection of the left Gasserian ganglion with 10 minims of 90 per cent. alcohol produced total trigeminal anaesthesia of all three divisions, with immediate cessation of the pain and tenderness.

Case 5.—A man aged 55 was seen in March, 1936, for pain affecting the whole of the left side of the head. For several months past he had had occasional bleeding from the nose, and neuralgic pain in the left side of the nose and across the cheek to the ear for three or four hours every afternoon. Turbinotomy gave no relief; another ear, nose, and throat surgeon found the left antrum opaque and removed a piece of growth, which was reported to be sarcoma. There was some numbness and partial anaesthesia of the left lower lip and half of the tongue, and also Eustachian deafness. The pain was controlled to a certain extent by taking sixteen veganin tablets daily. Alcohol injection of the outer two-thirds of the Gasserian ganglion was done by the lateral route on May 25, 1936, producing total anaesthesia of the left second and third trigeminal divisions, and immediate disappearance of all pain in the face.

Case 6.—In July, 1935, this patient, a man aged 59, complained of sore throat, and a piece of tonsil removed proved

to be malignant. He was exposed to heavy radium treatment for 138 hours, and felt completely cured. Six months later the symptoms returned, and he was again similarly treated for fifty hours; in addition five radium needles were immediately afterwards inserted into the left tonsillar region for five days. Pain of a neuralgic shooting character started at once, and persisted continually afterwards in both left upper and lower jaws and side of the tongue, the pain spreading into the left ear and temporo-mandibular joint, with occasional intermissions. The jaws became fixed from contracture due to a radium burn close to the temporo-mandibular joint. It appeared to me that the acute onset of the pain immediately following the second heavy radium treatment was due to a trigeminal neuritis and probably glosso-pharyngeal neuritis, also secondary to the radium treatment. Left Gasserian injection, producing complete trigeminal anaesthesia, relieved the lower jaw pain, but neuralgia persisted from the ear to the maxilla and temple, probably glosso-pharyngeal in origin. This nerve was then dissected out behind the angle of the jaw and avulsed from its point of emergence from the base of the skull. Though his pain was relieved he unfortunately developed pyrexia and increasing weakness, dying three days later.

Case 7.—A man aged 73 had suffered from a chronic left antral discharge following an antral operation forty years previously. Severe pain in the left side of the face began in January, 1937, and when seen by an ear, nose, and throat surgeon a diagnosis of carcinoma was made. Deep x-ray therapy produced some improvement, though the pain was just as severe six months later. Radium needles were inserted, but the disease advanced, a large perforation in the palate being visible and the cheek being much swollen and discharging pus. The whole area of the cheek and jaw was intensely hyper-sensitive to touch. I saw him with his doctor on March 25 this year, and on the next day, under ethyl chloride anaesthesia, I injected his left Gasserian ganglion by the anterior route. Owing to the great swelling of the cheek the needle had to be inserted rather lower than usual, but no particular difficulty was encountered, and total trigeminal anaesthesia resulted. This persisted unaltered on the following day, when all the facial hyperaesthesia had disappeared, and the parts could then be handled with impunity.

These seven cases of malignant growth involving the antrum, maxilla, or tonsil illustrate the great relief to the pain that can be obtained by a well-placed alcohol injection in the Gasserian ganglion. No doubt the same relief could be secured by a sensory-root resection of the fifth nerve or by a trigeminal tractotomy, but owing to the severity of these open operations they will probably be generally held unjustifiable in view of the weak state of the patients and their short expectation of life.

Carcinoma of the tongue that is considered to be inoperable owing to spread of the disease in the floor of the mouth or from recurrence after operation or radium treatment also causes great suffering from pain in the face, which may be relieved by a less extensive injection than the type described above. Alcohol injection of the third trigeminal division at the foramen ovale will anaesthetize the area of the disease and give complete relief to the pain without pushing on the needle into the Gasserian ganglion. The anaesthesia of a well-placed injection should last as long as the patient's expectation of life.

Case 8.—In January, 1936, this patient, a woman aged 55, had been treated by radium needling for carcinoma of the tongue, but severe pain persisted along the left side of the mandible as far as the middle of the chin, and the tongue was very painful on moving. For the past twenty years she had complained of a "sore ear," being unable to sleep on that side, with pain around the ear following exposure to a draught. This I considered to be a "geniculate neuralgia" following a chill neuritis, though another neurologist who had seen her thought the pain was glosso-pharyngeal in origin and unsuitable for injection. However, alcohol injection of the foramen ovale ended her jaw and tongue pain completely, leaving

untouched the otic or geniculate neuralgia, to which she had become quite accustomed.

I have notes of three other cases of pain due to inoperable carcinoma of the tongue similarly treated by alcohol injection of the third trigeminal division, but their details are of no special interest.

Conclusion

I bring these cases forward to illustrate the great relief that it is possible to afford patients racked with the constant severe pain of inoperable growths in the tongue or jaws, by a treatment involving little or no shock, and one which can usually be done under local anaesthesia only.

RELATION OF HODGKIN'S DISEASE AND THE LEUKAEMIAS TO GASTRIC DISORDERS

BY

E. HARVEY, M.B., B.Ch., B.A.O.

Clinical Pathologist and Biochemist, Royal City of Dublin Hospital

Dr. Cramer's paper in the *Journal* of April 16, 1938 (p. 829), will, I hope and believe, prove a landmark in the history of our ideas with regard to the aetiology and treatment of at least certain forms of cancer. My observations, for whatever they are worth, entirely confirm all that he says with regard to gastric (and indeed intestinal) cancer. I have some reason also for thinking that Hodgkin's disease and the leukaemias may be diseases sequential to or coincidental with gastric derangement following on what Dr. Cramer aptly terms "insult to the gastric mucous membrane." I give a brief summary of five case histories.

Case I

In August, 1936, a casual labourer aged 32 was admitted to hospital complaining of severe vomiting coming on after every meal, with abdominal pain, rapid loss of weight, thirst, and diarrhoea. He had very much enlarged cervical glands and enlargement of glands in the left axilla, with a clean smooth tongue. His medical history told of removal of the appendix somewhat over a year previously. He proved to be a typical case of Hodgkin's disease. Examination of his blood showed: haemoglobin, 95 per cent.; red cells, 5,475,000 per c.mm.; white cells, 7,800 per c.mm.; neutrophil polymorphs, 57 per cent.; eosinophil polymorphs, 1 per cent.; lymphocytes, 42 per cent. His usual diet was stated to be: Breakfast—white bread and butter, very strong tea, sometimes an egg or bacon; dinner—stewed beef and potatoes, white bread and butter, very strong tea; evening meal—white bread and butter, very strong tea; supper—a repetition of the evening meal. Curiosity was evoked by this dietetic history, and a test meal was given. It showed the absence of free hydrochloric acid in all specimens. As a consequence of this finding it was thought worth while to try the effect of injections of campolon, in addition to the hospital dietary and deep x-ray treatment of the enlarged glands. How far the campolon helped him is only conjectural, but he improved much in his general condition, with loss of pain and vomiting, increase of weight, etc., so that eventually he left the hospital on the understanding that he would come weekly for inspection to the out-patient dispensary. His subsequent history, however, was that of sudden serious relapse necessitating immediate removal to another hospital, where, I fear, death ensued quickly.

Case II

A carpenter aged 37 was admitted to hospital in August, 1937, complaining of loss of weight and strength, with quick fatigability and frontal headaches following on an attack of influenza six months previously. There were also intermittent pains in the back and legs, with profuse perspiration at times, a tendency to constipation, and great distension after meals. He had a jaundiced colour, which he stated had been constant for five years previous to admission. The glands in the left cervical and right and left inguinal regions were greatly enlarged: the patient had first noticed them two months previously.

There was a previous medical history of measles, whooping-cough, and tonsillectomy. He had been "pernickety" regarding food all his life, with little appetite for dinner but a good appetite for breakfast and the evening meal. He was very fond of strong tea, had indulged heavily in whisky, and had some addiction to stout and the moderate use of tobacco. The urine for some time after admission was ammoniacal and was positive to Ehrlich's urobilinogen test. Blood examination showed: haemoglobin, 74 per cent.; red cells, 2,900,000 per c.mm.; white cells, 3,400 per c.mm.; polymorphs, 52 per cent.; lymphocytes, 48 per cent. Anisocytosis was somewhat marked. This would indicate pernicious anaemia, while the glandular condition was one of Hodgkin's disease. A test meal showed free hydrochloric acid and total acid within fairly normal limits. The patient was put on campolon and collorion, with deep x-ray therapy over the enlarged glands. He responded poorly to treatment. One month after admission examination of his blood showed: haemoglobin, 59 per cent.; red cells, 2,350,000 per c.mm.; white cells, 5,100 per c.mm.; polymorphs, 63 per cent.; lymphocytes, 37 per cent.; and megalocytosis. Later he sank rapidly and died.

Case III

In February, 1938, a signalman aged 59 was admitted to hospital complaining of a very large "lump" in the abdomen which was incapacitating him from work. On examination the "lump" was seen to be an enormously enlarged spleen extending well to the right of the umbilicus and down to the inguinal ligament. The liver was also enlarged about two fingerbreadths below the costal margin in the mammary line.

A blood examination on February 4 showed: haemoglobin, 69 per cent.; red cells, 3,320,000 per c.mm.; white cells, 214,000 per c.mm.; polymorphs, 3 per cent.; premyelocytes, 97 per cent.; slight anisocytosis and poikilocytosis. The diagnosis of myelogenous leukaemia was made. On inquiry a history of daily vomiting before breakfast for eight to nine years previously was elicited. His diet had been: breakfast—4 to 5 oz. of white soda bread, a plain boiled egg, two cups of strong tea with two drachms of sugar to each cup; 10 to 11 a.m.—4 to 5 oz. of white soda bread, one cup of strong tea with two drachms of sugar; dinner, 2 p.m.—potatoes boiled in jackets, fried steak up to 8 oz., cabbage or turnips cooked with soda, one cup of strong tea with two drachms of sugar; evening meal, 4 to 5 p.m.—same as for breakfast, omitting the egg. Occasionally oatmeal porridge with milk was taken for breakfast. No alcohol was drunk, but 1½ oz. of tobacco was smoked weekly. The history of vomiting, and the very avitaminous diet, with the strong tea superadded so constantly, led to a test meal being given. It showed no free hydrochloric acid in any specimen. The patient received hospital diet with deep x-ray treatment over the enlarged spleen. His white cell count decreased rapidly, and on March 30 a blood examination showed: haemoglobin, 85 per cent.; red cells, 4,700,000 per c.mm.; white cells, 4,500; neutrophil polymorphs, 22 per cent.; eosinophil polymorphs, 2 per cent.; premyelocytes, 76 per cent.; red cells, regular.

On April 7 a further test meal was given. Again there was no free hydrochloric acid in any specimen. Parallel to the decrease in the white blood cell count was the rapid

decrease in the size of the spleen. Eventually it was considered that the patient was fit to resume work, and he was discharged from hospital.

Case IV

In February, 1938, a herdsman aged 65 was admitted to hospital complaining of weakness, tiredness, and inability to work—the condition dating from several years previously. He was seen to have large discrete glands in the neck and axillae, with a slighter enlargement of the inguinal glands. Blood examination on February 9 showed: haemoglobin, 79 per cent.; red cells, 4,500,000 per c.mm.; white cells, 19,400 per c.mm.; polymorphs, 5 per cent.; lymphocytes, 95 per cent. A diagnosis of lymphatic leukaemia was made. The patient's diet had been: 6 a.m.—a cup of fairly strong tea with two drachms of sugar and a slice of white bread and butter; 9 to 10 a.m.—a rasher of bacon and two fried eggs, or two boiled eggs, plenty of white bread and butter, two cups of strong tea with four drachms of sugar; 2 to 3 p.m.—boiled bacon and cabbage or turnips or parsnips, potatoes boiled in jackets, rarely beef or mutton or fowl; 5 p.m.—white bread and butter, two cups of strong tea with four drachms of sugar; 8 to 9 p.m.—flaked oats porridge with 1 pint of milk, or porridge made with buttermilk. When at fairs—that is, about once a fortnight—he took a great deal of draught porter or whisky. He used 5 to 6 oz. of tobacco a week. A test meal was given; this showed no free hydrochloric acid in any specimen.

The patient was given deep x-ray treatment, and his white cell count on March 31 was 5,800 per c.mm., with 82 per cent. lymphocytes. The enlarged glands decreased a great deal in size as the result of the treatment, but he grew gradually weaker, and died on April 11.

Case V

A man 66 years of age, caretaker of a forest wood, was admitted to hospital towards the end of February, 1938, with a greatly enlarged spleen and a history of periodical attacks of vomiting with pain in the left side. He had had paralysis of the right side about two and a half years previously from which he had never wholly recovered.

Examination of the blood on February 23 showed: haemoglobin, 61 per cent.; red cells, 2,194,000 per c.mm.; white cells, 159,000 per c.mm.; neutrophil polymorphs, 31 per cent.; neutrophil myelocytes, 50 per cent.; eosinophil myelocytes, 1 per cent.; transitional myelocytes, 12 per cent.; lymphocytes, 26 per cent.; nucleated red cells, 4 per cent.; anisocytosis and poikilocytosis. The diagnosis of myelogenous leukaemia was made and the patient was given deep x-ray therapy.

Inquiry into his diet seemed to show that there was nothing very unhygienic in his present mode of living, but he said he had always been able to eat well until lately, and that at one time he ate up to a pound of beefsteak at dinner. He had also in the past been taking stout very freely, and had smoked heavy "twist" tobacco up to 5 or 6 oz. a week. He was given a test meal on February 25, when no free hydrochloric acid was found in any specimen. Under x-ray treatment his white cell count fell to 32,750 per c.mm. on March 30, with 76 per cent. neutrophil polymorphs. His spleen also decreased in size under the treatment, but his general condition remained poor, and it was not considered advisable to give him further x-ray treatment for the present. He was advised to go home and come up later for inspection with a view to a repetition of the treatment if he was able to undergo it.

Comment

Here were five successive cases of glandular or splenic enlargement, all with dietetic histories which seemed to the clinical pathologist to warrant examination of test meals. In some cases there seemed to be positive abuse of the stomach by strong tea (and tea is often used in Ireland with very high tannic acid content), or alcohol,

or tobacco, or excessive amounts of food, etc. In general, too, the diets of these patients tended to be very avitaminous. Anyway, in four out of the five cases the test meal showed complete achlorhydria, while in the fifth case, although free hydrochloric acid and total acid were present in normal amount, the patient's blood seemed to disclose a state of pernicious anaemia. The two cases of myelogenous leukaemia tended also to have a colour index greater than unity. The number of cases, no doubt, is too small for any generalizations to be made, but they seem well worth presenting in the hope that other clinical pathologists may be induced to examine patients suffering from Hodgkin's disease or leukaemia, with a view to eliciting the state of the gastric mucous membrane and the previous dietetic history. If any considerable proportion of such patients show gastric anomalies comparable to those now being recorded there will be fair justification for thinking that the aetiology of these diseases runs somewhat on the same lines as Dr. Cramer believes to be true in the case of cancer of the stomach (and intestine?). Quite possibly, as in the case of cancer, we may have to consider how far a virus factor may also be involved. Dr. M. H. Gordon and his co-workers have adduced good evidence that a virus is at work in the case of Hodgkin's disease. Yet, as in the case of cancer—assuming the truth of Dr. Cramer's conception—it may be possible to prevent Hodgkin's disease in the future by a more strict attention to what dietetic hygiene is teaching us, or will teach us when its laws are more perfectly known. And the same may be true of leukaemias. Indeed, with regard to the latter, one cannot but think that they may be in some way analogous to pernicious anaemia. Just as in pernicious anaemia a degradation of the mucous membrane of the stomach (whatever may be its cause) makes the manufacture of haemopoietin impossible, with consequent inability of the bone marrow to produce mature red blood cells, so in the leukaemias some other anomaly of the gastric mucous membrane may be responsible for the flooding of the blood stream by the bone marrow with myelocytes or lymphocytes. We hope we shall yet learn to cure the leukaemias (and Hodgkin's disease) as we have learned to cure pernicious anaemia. If the work of van Rooyen regarding the effect of x rays on the virus of Hodgkin's disease *in vitro* is to be taken as correct, I fear we must turn our attention to the discovery of some other mode of treatment of that disease than by use of x-ray therapy. But meanwhile, or concurrently, we may perhaps learn to prevent it (and the leukaemias), just as Dr. Cramer thinks we ought to be able to prevent gastric cancer.

I am indebted to Dr. A. Parsons, F.R.C.P., physician to the Royal City of Dublin Hospital, under whose care the patients were admitted, for permission to write up these case histories in so far as they bear on the subject of this paper.

The University College Hospital report on radiotherapy for 1937, by Drs. Kenneth C. Eden and C. H. Offord, is upon the same lines as its predecessors. During the year under review the radiotherapeutic department has been entirely separated from that of radiodiagnosis. In general, the technique adopted remains the same as in previous years, except that the 1-gramme mass unit of radium has been replaced by a 2-gramme unit, and a new apparatus for superficial therapy has been installed to replace that which has been in use since 1920. During the period considered 567 patients were treated; of these 431 were new patients, including 250 cases of malignant disease. The total number of treatments given has risen from about 500 in 1930 to nearly 9,000 in 1937.

THE BIOLOGICAL SIGNIFICANCE OF THE TONSILS AND ADENOIDS AND OTHER EXTERNAL LYMPHOID MASSES

BY

PERCIVAL W. LEATHART, B.A., M.B., B.Ch.

Senior Surgeon, Eye and Ear Infirmary, Liverpool

In the wall of the pharyngeal cavity and intestinal canal numerous masses of lymphoid tissue are situated; they are not wholly enclosed in the tissues of the body, and for that reason may for descriptive purposes be termed "external lymphoid masses." Some of the larger masses have received names—the tonsils, the adenoid mass, and Peyer's patches; each is so situated that one of its surfaces is in contact with food or air, the remainder being buried in the tissues. Like other organs an external mass has an arterial and a venous blood supply through which it receives the material necessary for its special metabolism and from which by osmosis and filtration its lymph supply is derived. It possesses an efferent vessel through which lymph is conveyed to an adjacent node, but, unlike lymph nodes, it has no afferent lymph vessel. This anatomical peculiarity is of some importance, and will be referred to later.

The lymphoid tissue of the larger external masses is arranged so that folds alternate with fissures like the gyri and sulci of the cerebral cortex, or so that deep crypts lead inwards from its surface. Between the folds or in the crypts living micro-organisms are always found, except of course in the case of the newly born infant. It will thus be seen that an external mass has three salient features: (1) one surface is in contact with food or air; (2) it only possesses an efferent lymphatic channel which leads to the adjacent nodes; (3) the crypts contain living micro-organisms.

The Function of the External Lymphoid Mass

The external mass selects its inhabitants from food or air, and these flourish there to a greater or lesser extent. During its growth a micro-organism produces its specific toxin, which must be removed if growth is to continue. There are three routes by which this removal can be accomplished. The toxin may pass either (1) into the pharynx or intestine; (2) through the efferent lymph vessels into the lymphatic system; (3) direct into the blood stream. The following clinical evidence shows that the toxin is able to pass through the efferent lymph vessel into the lymph system and thence eventually into the blood stream.

It is well known that in the common air-borne infection called acute tonsillitis and in the food-borne infection typhoid fever, the external mass involved, be it tonsil or Peyer's patch, becomes inflamed, increases in size, and on it an exuberant growth of micro-organisms ensues. After a short interval the temperature of the body is raised, indicating that the toxins have passed into the blood stream. In addition, the lymph nodes in the vicinity of the external mass have become enlarged and sometimes tender. Since, as we have seen, an efferent lymph vessel passes from the external mass to the nodes we may conclude that the toxin has chosen this pathway into the lymphatic system and thence into the blood stream. It is not uncommon for nodes to suppurate, and when this occurs the specific organism in the external mass can be recovered from the abscess. Similarly the *B. typhosus* has been recovered from a Brodie's abscess and even from the "rose" spots in the acute stages of that disease. It is

clear, therefore, that when inflamed an external mass admits not only toxins but also micro-organisms into the lymphatic system which may form colonies in lymph nodes. But living micro-organisms are also to be found in all healthy external masses, consequently, their toxins too are being formed and removed unceasingly. It is obvious that the amount of toxin passed into the lymphatic system both in health and in disease bears a direct relation to that formed in the external mass at any given time.

Granted that an external mass is performing a positive function, we may define an external mass as one whose function is to cultivate micro-organisms deposited on its surface with the object of admitting some of them or their toxins, or both, into the lymphatic system and thus into the blood stream. The biological application of this definition will be clear from a consideration of the following facts.

It will readily be conceded that the common air-borne and food-borne infections are of more frequent occurrence in childhood than in adult life, that the child as he advances to the adult state contracts fewer and fewer infections, in spite of the fact that he is living generally under the same conditions as to food and air. He has by means of repeated infections and recoveries established an immunity, partial or complete, to many of the infections that still attack more particularly the younger members of the community in which he happens to live. The process by which this result is achieved may be termed "auto-immunization," the biological importance of which is evident, for by this means the adult population becomes relatively immune to infection current among the younger members of the community.

Particular stress is laid upon the fact that although any organism may be deposited upon an external mass, that external mass will only cultivate those to which the immunity of the individual is low or absent. In the case where immunity is complete, sufficient concentration of antibodies is present in the blood stream to prevent growth of organisms in the external mass. On the other hand, when immunity is low, growth takes place, toxin is absorbed, metabolic disturbance ensues, and the necessary antibodies are produced. It is clear, therefore, that external masses are extremely valuable organs and have a highly important biological function to perform in the establishment of a healthy adult population by auto-immunization of the growing child.

The Clinical Significance of Enlarged Tonsils and Adenoids

The removal of tonsils and adenoids is perhaps the commonest of all surgical procedures. Let us therefore review the situation with regard to the removal of tonsils and adenoids, bearing in mind clearly the function as defined above, its biological significance, and its medical implications.

At the present time children are often referred for removal of tonsils and adenoids for one or more of the following reasons: (1) enlarged tonsils alone; (2) enlargement with recurrent colds and mouth-breathing; (3) recurrent attacks of tonsillitis; (4) enlarged adenoids with chronic catarrh or suppurative otitis media. The operation is often performed when any one of these conditions is present, without a thought being given to the biological value of the tonsil and adenoid or to the ill effect which early removal may have on auto-immunization. In the first class of case, enlargement alone, there are frequently no other symptoms. The child is often sturdy and well nourished: his tonsils are enlarged because an organism is

present to which immunity is required in the interests of his future health. Auto-immunization is progressing satisfactorily, and when complete the tonsil will shrink in size from an enlarged, soft, succulent functioning organ to the fibrosed and atrophied organ of the adult.

In the second class of case the position is more complicated. Two additional conditions are present: these are frequent colds and nasal obstruction. It is generally taught, and believed, that both conditions are caused by an adenoid mass obstructing the post-nasal space—so much so that the term "adenoid facies" has crept into the literature. An adenoid mass large enough to obstruct an airway is certainly sometimes found, but, on the other hand, it is not unusual for almost complete nasal obstruction to exist although there is only a very small adenoid mass present, or for nasal obstruction to persist after its surgical removal.

What is nasal obstruction due to in these cases? Thorough investigation reveals (1) that nasal obstruction is due to rhinitis with congested and hypertrophied turbinates; (2) that on transillumination the sinuses are duller than normal on one or both sides. This has been confirmed repeatedly both radiologically and by exploratory puncture. The latter physical sign is invaluable, and is invariably present in such cases, being diagnostic of catarrhal sinusitis, and accounting for the rhinitis and the congested and hypertrophied turbinates so often seen in these children. This, therefore, would appear to be an adequate explanation of such cases of nasal obstruction: It is true that removal of adenoids in such cases sometimes restores nasal breathing and allows the catarrhal sinusitis to clear up; but this happy result is by no means common—failures are often experienced. It is doubtful, even in the apparently successful cases, whether permanent benefit has been secured. In any event an organ of biological value has been removed.

That catarrhal sinusitis should be diagnosed is important, for, apart from the symptomatic relief its cure affords, this condition is the precursor of many other medical conditions which lead to chronic ill-health, such as bronchial asthma, bronchitis, and bronchiectasis. It is also a direct cause of discharging ears and middle-ear deafness. It has been found that the conservative methods adopted at the Royal Liverpool Children's Hospital in preference to the radical removal of adenoids have yielded excellent results during the last few years.

A Plea for the Conservative Treatment

The treatment referred to is the administration of small doses of potassium iodide over a period of three months—1 to 3 grains once a day, according to the age of the child. Potassium iodide causes an increased secretion from the mucous membrane of all the nasal sinuses, as is evidenced by the greater amount of watery discharge seen in cases of catarrhal sinusitis so treated. Given over a period of at least three months it is an excellent "nasal aperient." As will be seen from the accompanying table there are failures, but the results as a whole compare favourably with those treated in a more radical manner. In 70 per cent. of those so treated it was seen that cases of enlarged tonsils and adenoids with nasal obstruction were transformed to cases of enlarged tonsils and adenoids only. Where no improvement was observed operation was considered.

In the third type of case, in which there are recurrent attacks of tonsillitis, it is difficult to make a decision for or against operation. It should always be borne in mind that the child is acquiring auto-immunization through

repeated mild infections. Of course it is impossible to say how many attacks of tonsillitis will produce such an immunity. In the routine examination transillumination should never be omitted, and if this should reveal a concurrent sinusitis this condition should be treated as outlined above, before any operative measure is warranted. In the case of recurrent tonsillitis without a sinusitis, more especially in the adolescent and the adult, we must come to the conclusion that the tonsil is now harbouring an organism to which that individual cannot acquire an immunity. Here operation is advisable.

In the above category two other classes of case fall—namely, rheumatic fever and nephritis which are not responding to treatment. Here again auto-immunization has given place to auto-intoxication, and, such being the case, removal of tonsils is urgently indicated. It will be noted that both conditions usually begin as a tonsillitis; that when the case is examined either the initial tonsillitis is not apparent or the acute stage has passed off and consequently the tonsillitis cannot be detected by inspection only. However, enlarged and/or tender glands can invariably be detected in the anterior triangle, showing that the micro-organisms or their toxins (or both) responsible for those conditions are still being absorbed and damaging the kidney or the heart. It is clear that in such cases removal of the tonsils which are harbouring these organisms is now a necessity.

The remaining indication for removal of adenoids is in those cases of chronic catarrhal otitis media and persistent otorrhoea where it is claimed by some clinicians that the enlarged and infected adenoid mass is retarding the improvement of the middle-ear infection.

Cases Operated on after Potassium Iodide Treatment

| Period Under Review | No. of Cases Under Observation | No. of Cases where Operation was Primarily Indicated | No. of Cases Operated on After Potassium Iodide Treatment |
|---------------------|--------------------------------|--|---|
| 1928 | 426 | 9 | 170 |
| 1929 | 369 | 19 | 141 |
| 1930 | 300 | 11 | 83 |
| 1931 | 376 | 9 | 105 |
| 1932 | 358 | 22 | 76 |
| 5 years | 1,829 | 70 | 575 |

The cases operated on after treatment with potassium iodide, excluding those in which operation was primarily indicated, amount to 30 per cent. The number successfully treated by potassium iodide is 70 per cent.

Conclusions

1. That the function of an external lymphoid mass is to collect micro-organisms from food or air and to grow those to which an immunity is needed.
2. That the condition "enlarged tonsils" alone is definitely an indication against their removal.
3. That the adenoid facies is more commonly caused by catarrhal sinusitis than by an adenoid mass.
4. That catarrhal sinusitis can be treated successfully in a large number of cases without operation, by giving a "nasal aperient."
5. That tonsils and adenoids at the present time are removed too frequently and without due consideration of their important biological function.
6. That many cases of rheumatic fever and acute nephritis that are going downhill can be cured or greatly benefited by removal of the "carrier organ."

Clinical Memoranda

Idiopathic Epilepsy from Another Aspect with Treatment of the Fit

It has been an accepted fact for many years that the epileptic fit is the result of a sudden discharge of nervous energy from the cerebral cortex. However, apart from certain reflex phenomena, such as worms in children, no cause has been described either clinically or pathologically.

Bearing in mind the absence of any constant pathological cerebral changes, and viewing the condition from all aspects, one cannot help being struck by the features which are the manifestations of the phenomenon known as the epileptic fit. These features are the uniformity in the characteristics of the prodromal symptoms and of the fit itself, these being very similar, if not identical, in the one individual. This orderly sequence of events suggests that the fit is a response to some unknown stimulus of equally unknown *modus operandi*, and therefore that the fit is really a phase of reflex activity in response to an exciting cause, the aura being merely the distant impressions caused by the mobilizing of a vast army of nervous impulses, the discharge of which may in reality be a protective mechanism on the part of the body.

What of the possibility that this unknown stimulus produces a spasm of certain of the arterioles supplying the brain substance, the local anoxaemia so caused being responsible for the generation of impulses which on discharge cause the convulsions? If this be the case it may be analogous to the convulsive movements seen in asphyxia just before the stage of exhaustion: To test this theory it was resolved to experiment with the well-known vasodilator amyl nitrite in the next case seen.

EXPERIMENTAL CASES

This patient was a girl aged 11 with a history of epilepsy from early childhood. The attacks usually occurred monthly, and the common method of administering a general anaesthetic had always been employed. According to custom, the child was put fairly deeply under with ethyl chloride and maintained thus for some minutes. On regaining consciousness she appeared to have recovered, and, the parents being satisfied that the fit was over, further attention was unnecessary. Seven hours later there was another call to the child, who, after sleeping quietly for some hours, had another fit, and when seen was in status epilepticus. It was then resolved to try out the above theory of vascular spasm. One 3-minim ampoule of amyl nitrite was broken and held for the patient to inhale. A dramatic effect followed. The attack ceased almost immediately and, after regaining consciousness for a few minutes, the patient fell into a deep sleep.

Following this apparent success, an ampoule was given to a man, aged 35, who invariably had a fit when the moon was full. He was instructed to use the drug immediately he experienced the aura, and also to inform a relative of it. Unfortunately the patient's aura never gave him adequate warning. However, his mother administered the drug, with the satisfying result that he recovered in about a quarter of the usual time.

Although my experiments have been very limited, I thought it worth while to record the cases in the hope that the drug might be tried on other epileptics, especially those whose aura gives them fair warning of the approaching fit, and thus render them a service similar to that experienced by those who suffer from angina pectoris.

Edinburgh.
